

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

- + *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
- + *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
- + *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
- + *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter <http://books.google.com> durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

Medical men, deaths of eminent foreign, 72, 136, 260, 452, 511, 720, 783, 845, 964, 1027, 1158, 1406; number of, in Paris, 259; and insanity in relation to law, 300; unfounded charges against, 655, 714, 766, 899, 1025, 1221; and journalistic interviews, 716; pecuniary rewards of, 879; in their dealings with public bodies, 898; in Alsace-Lorraine, 900; advertising by, 960; and advertised foods, 1163; actions against, for unskillful treatment and for libel, 1221; actions against, for mistake in diagnosis, 1279; the sweating of, 1399

Medical Congress at Rome, the International, proceedings of the, 49, 1439

Medical Congress, German, in Munich, 429, 946, 949, 1004, 1008

Medical Congress, Indian (see Indian Medical Congress)

Medical home, a, wanted, 1680

Medical magistrates, 1676

Medical officers of health, reports of, 61, 62, 431, 773, 777, 778, 835, 1009, 1140, 1210, 1393,

1457, 1601; reports of the, a suggestion, 639; reappointment of, 1002; officer of health, tenure of the appointment of, 110; officer of health, opening for, in Cape Colony, 454; officer of health of the administrative county of London, annual report of the, 1451, 1659; Officers' Association, Poor-law, petition of the, 630; officers in county hospitals, the appointment of, 709; officer, Poor-law, locum-tenent of, 714; officer, district, the remuneration of, 965; officer, Poor-law, in Ireland, 842, 1219

Medical officers' (Cork) indemnity fund, 1672

Medical profession, new year's honours to the, 44; increase of the, 109; and the stores system, 239; and Freemasonry, 245, 255, 491, 654, 1091, 1615; the "sweating system" applied to the, 761; its place and progress, an address on, 973, 1056; Mr. A. J. Balfour on the, 1322; birthday honours to the, 1384; Professor Brouardel on the, 1447; the easy accusation of the, 1451

MEDICAL SOCIETIES.

ÆSCULAPIAN SOCIETY.—Exhibition of cases; Strangulated hernia; Diphtheria, 289—The action of cardiac tonics; Diphtheria treated with antitoxin; Synopsis of 1000 cases of midwifery, 619—Exhibition of case and specimens; Morbus cordis, 1378

BOURNEMOUTH MEDICAL SOCIETY.—Acute dilatation of the stomach; Convulsions during pregnancy; Exhibition of cases, 196

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—The prevention of tuberculosis, 195—Exhibition of specimens; Bullet wound of the thorax; The use of increasing doses of bromides in cases of obstinate epilepsy, 413—Exhibition of cases, 814—Microcephalic idiosyncrasy; Exhibition of specimens, 720—Treatment of diphtheria by antitoxin; Traumatic stricture of the urethra; Tumour in the region of the sella turcica, 993—Exhibition of cases and specimens, 1254

BRIGHTON MEDICO-CHIRURGICAL SOCIETY.—Exhibition of cases; Uric acid gravel, 412

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—Inversion of uterus; Exhibition of cases and specimens, 583—Exhibition of cases and specimens, 752—Displacement of the gravid uterus; Tumour of brain; Exhibition of cases and specimens, 1054

BRITISH GYNÆCOLOGICAL SOCIETY.—Presidential address on the evolution of obstetrics and gynaecology; Exhibition of specimens, 466—Exhibition of specimens; The dangers of morphia in gynaecological practice; Leakage of an ovarian cyst in a girl aged thirteen, 749—Adjourned discussion on the dangers of morphia in gynaecological practice; Exhibition of specimens, 1057—Pregnancy complicated by suppurative within the pelvis; Exhibition of specimens; Intra-uterine stems, 1315

BRITISH ORTHOPÆDIC SOCIETY.—The causes of rotation in scoliosis; Exhibition of cases and specimens, 846—Talipes equinovarus; Exhibition of cases and specimens, 1616

CAMBRIDGE MEDICAL SOCIETY.—Salicylates in acute rheumatism, 156—Antitoxin treatment of diphtheria, 619

CATHOLIC UNIVERSITY MEDICAL SCHOOL: MEDICAL AND SCIENTIFIC SOCIETY.—Appointment of office-bearers, 252

CLINICAL SOCIETY.—Abdominal section for unusual conditions; Acute intestinal obstruction from gall-stone; Loculated empyema, 155—Detachment of the retina in chronic nephritis; Chronic self-inflicted ulceration of the throat; Association of respiratory paralysis with cardio-pulmonary symptoms in diphtheritic paralysis, 285—Cystic hygroma in an adult; Two cases of congenital dislocation of the hip treated by a new method; Syphilitic stenosis of pharynx, 409—Unusual case of diphtheria in the air passages; Case of malformation of heart, with hamophilia; Case of gangrenous umbilical hernia, successful resection with use of Murphy's button; Hysterical contracture of legs, 617—Cerebral tumour following injury; Association of psoriasis with diabetes; Rupture of gall-bladder and liver produced by violent straining in a patient suffering from obstructive jaundice; Traumatic cystic lympho-sarcoma of shoulder removed by amputation after five years' growth; Complete unilateral arrest of development in a child with areus scillitis and without hemiplegia, 679—Nephrectomy for renal adenoma; Cases illustrating local treatment by oxygen; Syringomyelia with perforating ulcer; Pseudo-bulbar paralysis; Facio-

humeral type of myopathy; Fracture dislocation of the spine; New form of aspirating instrument; Successful trephining for syphilitic cranial necrosis; Meningocele; A case of mycosis fungoides, 811—Abdominal section for intestinal obstruction caused by volvulus of the sigmoid flexure; Early erosion in inflammation of the sacroiliac joint; Orchiotomy for enlargement of prostate; Large intra-thoracic cystic goitre causing dyspnoea and treated by operation, 1116—Absence of abdominal muscles in an infant; Extensive degenerating nevus of bladder; Gastric ulcer treated by laparotomy, 1252—Thickened and contracted mesentery simulating tumour in a case of cirrhosis of the liver; Splenic abscess associated with hepatic suppurative and death from pyæmia; Recovery from tuberculous meningitis; Calculus of kidney associated with simple growth in renal pelvis; Annual general meeting, 1315

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—Exhibition of cases, 785

DERMATOLOGICAL SOCIETY OF LONDON.—Annual meeting, 1349

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.—Exhibition of cases; Raynaud's disease; Intestinal obstruction, 32—Exhibition of cases; Aortic aneurysm; Resection of the intestine, 224—Cardiac therapeutics, 413—The adjourned discussion on cardiac therapeutics, 561, 621—Exhibition of cases; Treatment of suppuration in certain osseous cavities, 653—Palliative treatment of jaundice caused by malignant obstruction; Probable lesions in incipient caseous pulmonary phthisis; Exhibition of cases and specimens, 1189—Multiple diabetic neuritis; Skin grafting from the lower animals; Exhibition of cases, specimens, and drawings, 1316—Tuberculous pleurisy; Cobra venom; Exhibition of cases and specimens, 1516

EDINBURGH OBSTETRICAL SOCIETY.—Pseudo-hysteria in pregnancy; Clinical aspects of utero-sacral cellulitis, 118—Extra-uterine gestation; Methods of artificial respiration in the new-born; The mechanism of labour; Exhibition of specimens, 489—Frozen sections and the mechanism of labour, 753—The influence of the removal of the ovaries on metabolism; Vesico-vaginal fistula; The Biddenden maids; Exhibition of specimens, 1255—Chorea gravidarum; The blood of the newly-born child, 1582

EPIDEMIOLOGICAL SOCIETY.—Epidemic diseases in the Royal Navy, 228—Immunity, 1118—The relations between the conditions of the soil and the prevalence of epidemic and endemic diseases, 1314

GLASGOW EASTERN MEDICAL SOCIETY.—Medical men in their dealings with public bodies, 898

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—Office-bearers, 1343

HARVEIAN SOCIETY.—Exhibition of cases, 96—Presidential address, evolution in treatment from 1831 to 1895 (a sketch), 222—Relapsing typhoid, 487—Syphilitic diseases of the brain, 548—The dorsal auscultation of heart sounds and murmurs, 751—Exhibition of cases, 875—Clinical study of some of the more important forms of abscess, 991—Sympopal bradycardia, 1119—The surgery of the rectum, 1264—Splenic anaemia; Exhibition of cases, 1377

HUNTERIAN SOCIETY.—The operative treatment of perityphlitis, 221—The Hunterian oration on the microbe of malaria, 411—Exhibition of cases, 485—Annual general meeting, 553—Senile plethora, 654—Exhibition of specimens, 751—Rheumatoid arthritis, 875—Exhibition of cases, 1029—The necessity for a central organisation in the medical profession, 1313

INVERNESS MEDICAL SOCIETY.—Treatment of myxoedema and psoriasis with extract of thyroid gland, 91—Medical clubs and medical aid societies, 1381

KIDDERMINSTER MEDICAL SOCIETY.—Castration for enlarged prostate; A case of enterostomy; A case of cerebral abscess, operation, death; Malarial fever; Exhibition of cases and specimens; Fees under the Notification Act, 549—Removal of testes for enlarged prostate, with notes of two surgical cases; scarlet fever; Exhibition of cases, 1058

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—Relation between death from measles and house conditions; The disruption of impacted urinary calculi; Exhibition of cases and specimens, 224—Erratum, 291—

Mania following pleurisy; Operations on the mastoid process; Dilatation of the cervix uteri; Flexor spasm of hand; Exhibition of cases and specimens, 488—Exhibition of cases and specimens, 620—Ruptured tubal gestation; Enteric fever complicated by phlebitis and pleuro-pneumonia; Traumatic gluteal aneurysm; Exhibition of cases and specimens, 682—Impacted gall-stone; On certain abnormalities of convulsion and structure in the brains of the insane; Exhibition of specimens, 1058—Prognosis of cerebral hemorrhage; Symphysiotomy; Antitoxin treatment of diphtheria; Exhibition of cases and specimens, 1438

LIVERPOOL MEDICAL INSTITUTION.—Annual general meeting, 196—Glioma of the retina; Injury to the internal carotid artery, ligation of the common carotid, recovery; A case of acromegaly benefited by treatment; A case of anæsthetic leprosy; Successful trephining for meningeal hemorrhage; Pregnancy complicating fibroid tumour of the body of the uterus, 349—Exhibition of cases; Fourteen cases of excision of the rectum for cancer, 487—Myositis fungoides; Pneumonia with relapse; An unrecognised danger in the administration of chloroform; Course and treatment of acute rheumatic endocarditis, 619—Case of laryngeal paralysis; Death certification and the recommendations of the Select Committee of the House of Commons, 752—On the mental aspect of some traumatic neuroses; Exhibition of cases, 875—Lung cavity incised and drained; Two cases of cleft palate to show the natural voice some years after operation; Rhinoliths; Treatment of delirium tremens; Modern miracles of healing, 1059—Enterostomy for foreign bodies; Two cases of compound depressed fracture of the skull; Trephining for subdural hemorrhage; Eye cases; Painful digestion in chlorotic and hysterical persons, 1188

MANCHESTER MEDICAL SOCIETY.—Annual general meeting, 196—Recent advances in urinary surgery; Radical cure of hernia; Operation for ptosis, 454—Analysis of fifty-five cases of carcinoma of the breast; Exhibition of cases, 551—Case illustrating the difficulty of diagnosing the exact position of a pulmonary cavity; Nephrectomy; Typhoid fever; Renal surgery, 992

MANCHESTER PATHOLOGICAL SOCIETY.—Exhibition of specimens, 223—Osteomalacia subsequent to scirrhus of the mamma; Exhibition of specimens, 549—Epithelioma of the œsophagus with perforation into the trachea; Exhibition of specimens, 813—The relations between the structure of the liver and certain pathological lesions; Curious cutaneous products; Fractured cervical spine, 1254

MEDICAL SOCIETY OF LONDON.—Cycling and heart disease, 153—Lectsonian lectures on the combinations of morbid conditions of the chest, 201, 329, 471—A successful case of pericarditis pericardii; The treatment of empyema in children, based on an analysis of eighty-six cases, 265—Unusual maldevelopment of skull unassociated with cerebral symptoms; High excision of rectum; Cork in adult male bladder; Right hemiplegia with epilepsy treated by trephining; Pyloroplasty; Enteroplasty; Gastro-enterostomy; Pseudo-hypertrophic paralysis with preservation of knee-jerks, 408—Cases of liver and gall-duct surgery; Craniectomy, 547—Hysterical deafness; Thirty cases of nephrorrhaphy, 678—Annual dinner, 785—Tubal pregnancy and case simulating tubal pregnancy; Extra-uterine gestation operated on in the tenth month of pregnancy, 810—Congenital chorea; Facial hemiatrophy; Friedreich's disease; Case after removal of a papilloma of the bladder by suprapubic cystotomy; Syphilitic disease of both knee-joints; Large renal sarcoma from child aged three years; Subcutaneous nodules in an infant; Devergie's ptyriasis rubra pilaris; Rudimentary ear; Macrocheilia; Restoration of nose by means of transplanting part of middle finger of left hand, 931—Serous pleuritic effusion treated by multiple tapping and afterwards by incision; Sclerema neonatorum ending in recovery, 1056—Annual general meeting; The diagnosis of retro-peritoneal sarcoma; Series of operations on the stomach, 1251—Annual oration, 1289—Conversazione, 1329—Election of officers, 1350

MEDICO-PSYCHOLOGICAL ASSOCIATION.—A review of the last twenty years at the Worcester County and City Lunatic Asylum; Atrophy and sclerosis of the cerebellum; Influenza

as a factor in the increase of insanity in Ireland, 682

MIDLAND MEDICAL SOCIETY.—Exhibition of cases; Post-partum hemorrhage, 289—Exhibition of cases; An unusual form of anæmia, 412—Exhibition of cases and specimens; Etiology of Tumours, 683—Exhibition of cases and specimens; Some points in invalid dietetics, 813—Intra-peritoneal hemorrhage; Exhibition of cases and specimens, 1119

NEWCASTLE-UPON-TYNE CLINICAL SOCIETY.—Oxidisation in the tissues; annual dinner, 448

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—Annual dinner, 455—Exhibition of cases and specimens, 549—Selection of cardiac tonics; Treatment of psoriasis by thyroid extract; Aneurysm of the descending thoracic aorta in a female, 812—The medical profession, its place and progress, 973

NORTH-WEST LONDON CLINICAL SOCIETY.—Exhibition of cases and specimens, 156, 487, 1158, 1350

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—Exhibition of cases, 157

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—Cataract extraction, 128—House sanitation, 228—Ligation of the common carotid artery; Exhibition of cases and specimens, 519—Calcareous corpuscles of tapeworms; Exhibition of specimens, 583—Nephro-lithotomy and nephrorrhaphy, 784—Three cases of laryngeal paralysis; Graves' disease; Chronic pharyngitis; Some points connected with the question of operation in acute intestinal obstruction, 933—Infantile convulsions; Toxic affections of vision; Apparatus for the administration of anesthetics; Exhibition of case, 1189—Pernicious anæmia; Misplacement of abdominal viscera, 1157—Quinine poisoning; Intestinal obstruction; Exhibition of cases and specimens, 1378

OBSTETRICAL SOCIETY.—Peritonitis, its nature and treatment; Exhibition of specimens, 94—Some observations on the temperature, pulse, and respiration during labour and the lying-in; Annual general meeting, 410—President's address; The disintegration of organic tissue by high tension currents; Exhibition of specimens, 681—Temperature, pulse, and respiration during labour and lying-in; Ovariectomy in women over the age of eighty years; Exhibition of specimens, 932—The examination and registration of midwives, 1035—The common form of "white leg" occurring after childbirth; Exhibition of specimen, 1186—The development and normal structure of the human placenta; Exhibition of specimens, 1516

ONTOLOGICAL SOCIETY OF GREAT BRITAIN.—Office-bearers, 1554

OPHTHALMOLOGICAL SOCIETY.—Two cases of diphtheritic conjunctivitis treated by Klein's antitoxin; Removal of the lens in high myopia, with a case of -25 D; Eyesight and the public services; Exhibition of specimens, 347—Double optic atrophy with peculiar visual fields; Filaria loa; Traumatic cataract with a foreign body embedded in the lens; A form of iritis not usually recognised; Exhibition of cases and specimens, 748—A new operation for ptosis; Blood-staining of the cornea; Sudden severe hemorrhage from the conjunctival surface of the lid; Exhibition of specimens, 1187—Subjective visual sensations (Bowman lecture), 1564—Ophthalmia nodosa; Nine cases of chancre of the conjunctiva; Exhibition of specimens, 1644

PATHOLOGICAL SOCIETY.—Enlarged spleen; Five brains from insane patients; Serous pachymeningitis in a syphilitic child; Cancer of nanna, 154—Researches on the pneumococcus, with especial reference to immunity; Notes on the bacteriology and pathological chemistry of pneumonia, 346—Endosteal sarcoma of the patella; Fetus with reptilian characters in sexual ducts; Adenoma of lip; Portal thrombosis and hepatic infarction; Exhibition of specimens, 485—The pathology of diphtheria, 616—The immunisation of horses; Adjoined debate upon the pathology of diphtheria, 747—Carcinoma of ureter; Congenital obliteration of bile-duct; Sarcoma of breast; Carcinoma of bed of thumb-nail; Carcinoma of stomach; Duodenal ulcers in women; Cirrhosis of liver in child; Secondary intra-thoracic sarcoma; Exhibition of specimens, 873—Microscopic structure of oxalate of lime calculi; Results following the experimental

removal of portions of the kidney; Elongation of radius from osteitis deformans, 1184—Absorption and metabolism in a case of pancreatic obstruction; Observations and experiments on the pathology of Graves' disease; The relation of swine fever to general ulcerative colitis; Actinomycosis of cheek; Malignant reversion of cystic fibromata; Exhibition of specimens, 1311

PLYMOUTH MEDICAL SOCIETY.—Glaucoma; Exhibition of cases and specimens, 223; Injury to shoulder; Gastrotomy, 904

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Series of 100 cataract extractions; Method of restoring the lower lip after excision for cancer; Case of locomotor ataxia due to injury; Small-pox; Small-pox temperatures, 225—Spina bifida; Ovarian tumours; Clinical report of the Rotunda Lying-in Hospital, 290—Case of locomotor ataxia from injury; Small-pox; Some small-pox temperatures, 489—Microscopic sections of the central nervous system; Topographical anatomy of the pancreas; Cold-water starch as a basis for an injection mass in dissecting-room work; Retro-peritoneal rupture of the duodenum; Crystalline branched renal calculus removed by nephro-lithotomy; Fracture of the sacrum, 552—Intra-ligamentous cyst; Ovary and tube removed for pyosalpinx; Leucorrhœa, its causes, varieties, and treatment, 684—Symmetrical gangrene of ears; Cirrhosis of liver in a child, 753—Varicocele, nevus, and varicose veins of the leg; New operation for the cure of rotation inwards of the entire limb, 814—Hydroa gestationis; Friedreich's disease; Protracted typhoid fever, 876—The treatment of severe hemorrhage by the infusion of normal saline solution; Exhibition of specimens; A rare tumour; Fibro-myxoma of tongue; Denterigerous tumour of the neck; Orbital tumour; Malignant disease of the ear, 1059—Defective infantile life unrecognised by State medicine; Private hospitals or home hospitals, 1190—Excision of the rectum, 1317—Imperforate anus necessitating colotomy; Exhibition of specimens; Chronic articular rheumatism; Fracture of the tibia; Exhibition of specimens; Injuries involving the articulations of the metacarpal bone of the thumb, 1517

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Illustrations of some modes of death from ovariectomy, 93; Varieties of intestinal obstruction dependent on gall-stones, with a series of cases, 220; The causation of ægophony, 407; Discussion on the affections of the nervous system occurring in the early (secondary) stages of syphilis, 546; Annual general meeting, 615; Adjoined discussion on affections of the nervous system occurring in the early (secondary) stages of syphilis, 676; Nervous symptoms and morbid changes in the spinal cord in certain cases of profound anæmia, 808; Case of large pelvic hydatid successfully treated by perineal incision and drainage, 930; Pathological identity of the various forms of acute septic inflammations of the throat, 1055; Adjoined debate upon Dr. Semon's paper, 1250; Micro-organisms in the healthy nose, 1374—Special general meeting; Further observations on the development of mammary functions by the skin of lying-in women; Intra-peritoneal rupture of bladder successfully treated by suture, 1514

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—Cholecystectomy; Double optic atrophy; Sarcomatous tumours; Removal of the parotid gland; Exhibition of specimens; Rectal etherisation, 97—Poisoning by camphor; Exhibition of specimens, 324—Diphtheria and antitoxin, 454—Exhibition of cases and specimens; Chronic stricture of the urethra, 620—Traumatic aneurysm of aberrant right subclavian artery; A new method of dividing bone in surgical operations, 752—Jaundice; Exhibition of cases and specimens, 845—Exhibition of cases and specimens; Ectopia testis, 993

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—Municipal and sanitary administration; The limits of infection in phthisis, 96—The connexion between female labour in factories and the high infant mortality in certain manufacturing towns, 238—Adjoined discussion on the legal definition of sewers and drains, 992

TORQUAY MEDICAL SOCIETY.—Dilatation of the iris; Cerebral embolism; Exhibition of specimens, 98

ULSTER MEDICAL SOCIETY.—Auto-abdominal section, 1218

WEST LONDON MEDICO-CHIRURGICAL SOCIETY. Stations for the bacteriological examination of suspected cases of diphtheria; The treatment of epilepsy; The role of alcohol in heart disease, 96—Casual cow-pox; Intestinal affections requiring surgical treatment, 348—Exhibition of cases, 618—Treatment of empyema in children; Secondary malignant disease of the lung or pleura, 933—Antipyretics, their use and abuse; The recognition and treatment of peripheral neuritis, 1188—Annual dinner, 1412—Fracture of the extremities in old people; Intra-cranial tumour; Exhibition of cases, 1582

CHARING-CROSS HOSPITAL.—Enucleation of hydatid cyst of liver; recovery; remarks (under the care of Mr. John H. Morgau), 344

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY.—An unusual case of Addison's disease; sudden death; remarks (under the care of Mr. Paul Star), 284

CROMER COTTAGE HOSPITAL.—Traumatic aneurysm; ligation of the axillary artery; remarks (under the care of Mr. Fenner), 92

DERBYSHIRE ROYAL INFIRMARY.—A case of advanced meningitis; craniotomy; recovery; remarks (under the care of Dr. C. A. Greaves), 746

DONCASTER GENERAL INFIRMARY AND DISPENSARY.—Aneurysm of the aortic arch in a young woman; necropsy; remarks (under the care of Dr. A. C. Wilson), 990

EAST LONDON HOSPITAL FOR CHILDREN.—A case of accidental ablation of the leg without fracture; amputation at the thigh; remarks (under the care of Dr. Ernest E. Ware, late resident medical officer), 92

EMSWORTH COTTAGE HOSPITAL.—Case of anorexia nervosa; necropsy (under the care of Mr. Lockhart Stephens), 31

GRIMSBY HOSPITAL.—Case of perforating wound of the right pleura; recovery, 1643

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.—Sloughing of urethra from pressure by a metallic ring; plastic operation; recovery; remarks (under the care of Mr. Edmund Owen), 150

KING'S COLLEGE HOSPITAL.—A case of floating kidney with intermittent hydronephrosis cured by fixing the kidney in the loin (under the care of Mr. Watson Cheyne), 806—Four cases of tuberculous disease of the bladder treated by supra-pubic cystotomy; remarks (under the care of Mr. W. Watson Cheyne), 1579

LEEDS GENERAL INFIRMARY.—A case of necrosis of the tibia of eight years' duration, with lengthening of the affected bone and the fibula of the same side; remarks (under the care of Mr. W. H. Brown), 1310—A case of symphysiotomy; remarks (under the care of Dr. Braithwaite), 1437—Intestinal anastomosis by the Murphy button for relief in an advanced case of cancer of the colon and stomach; necropsy; remarks (under the care of Dr. A. G. Barrs and Mr. Mayo Robson), 1513

LEEDS HOSPITAL FOR WOMEN AND CHILDREN.—A case of osteomalacia; remarks (under the care of Dr. J. B. Hellier), 807

LONDON HOSPITAL.—Two cases in which small suppurated ovarian cysts were easily enucleated and removed entire (under the care of Dr. Herman), 613—Tuberculous ulceration of the bladder treated by supra-pubic cystotomy and cauterisation (under the care of Mr. C. Mansell Moullin), 1306

LOUGHBOROUGH AND DISTRICT GENERAL HOSPITAL AND DISPENSARY.—Ovariectomy for multilocular cyst; recovery, complicated by femoral hernia; remarks (under the care of Mr. J. B. Pike), 1514

MANCHESTER ROYAL INFIRMARY.—Secondary hæmorrhage in a case of acute periostitis of the femur; ligation of the common femoral artery; recovery; remarks (under the care of Mr. F. Southam), 1309

MIDDLESEX HOSPITAL.—Two cases of operation for cystic bronchocele; remarks (under the care of Mr. Henry Morris), 28—Cancer of rectum; inguinal colotomy; pregnancy; Caesarean section; recovery (under the care of Dr. Wm. Duncan), 405—A case of congenital dilatation of both ureters; right ureterotomy and left nephrotomy in a newborn child; remarks (under the care of Mr. H. Morris), 1435

NEWCASTLE-UPON-TYNE ROYAL INFIRMARY.—Two cases of stone in the bladder where primary union of the bladder wound occurred after supra-pubic lithotomy; remarks (under the care of Mr. F. Page), 93—A case of cut-throat involving the larynx treated by suturing; complete primary union; remarks (under the care of Dr. Arnison), 284—Cases of operation for gall-stones through a transverse incision (under the care of Dr. G. H. Hume), 406

NORTH DEVON INFIRMARY.—A case of injury to the abdomen and left lung; frequent aspirations, with subsequent recovery; remarks (under the care of Mr. J. R. Harper), 872

NORWOOD COTTAGE HOSPITAL.—Abdominal section; enucleation of pelvic uterine fibroid; suturing posterior uterine wall; recovery, 1643

NOTTINGHAM GENERAL HOSPITAL.—A case of tumour of the corpora quadrigemina; necropsy; remarks (under the care of Dr. W. B. Ransom), 1115

ROYAL BERKSHIRE HOSPITAL.—Perforation of a gastric ulcer; operation; recovery; remarks (under the care of Mr. J. Hopkins Walters), 484—Case of double basilar pneumonia associated with pregnancy, heart disease, and bronchitis, and followed by empyema; resection of ribs; recovery; remarks (under the care of Dr. F. Hawkins), 989—Case of bilateral paralysis of the arytenoid posterior associated with tabes dorsalis; asphyxia; tracheotomy; recovery; remarks (under the care of Dr. F. Hawkins), 1373

ROYAL FREE HOSPITAL. Acute intussusception in an infant aged four months; laparotomy; recovery; remarks (under the care of Mr. E. W. Roughton), 437—A case of disease of the middle ear in which a resulting temporo-sphenoidal abscess discharged through the nose, 1642

ROYAL SOUTH HANTS INFIRMARY.—A case of cerebellar abscess following suppuration in middle ear, with a polypus in the external meatus; remarks (under the care of Dr. J. L. Thomas), 1249

ROYAL VICTORIA HOSPITAL, NETLEY.—Bony ankylosis of hip-joint; malposition; osteotomy; recovery with useful limb; remarks (under the care of Surgeon-Major Whitehead), 152

SAFFRON WALDEN HOSPITAL.—A case of left pyonephrosis; intestinal obstruction; unusual symptoms; nephrectomy; recovery; remarks (under the care of Mr. Hedley Bartlett), 675

ST. BARTHOLOMEW'S HOSPITAL.—A case of obstinate pleuritic effusion with negative pressure in the pleura; accidental pneumothorax; recovery; remarks (under the care of Dr. Samuel West), 674—Two cases of exophthalmic goitre in sisters, with morbus cordis and a history of rheumatic fever in both; remarks (under the care of Dr. Samuel West), 1248

ST. GEORGE'S HOSPITAL.—An exceptional case of epithelioma of the tongue in a woman; removal; recurrence; death in ten months (under the care of Mr. Warrington Haward), 543

ST. MARY'S HOSPITAL.—Obscure "renal symptoms"; cancer of ascending colon; resection; death; remarks (under the care of Mr. Edmund Owen), 1054

ST. THOMAS'S HOSPITAL.—A case of traumatic intra-peritoneal hemorrhage without external wound; hamatohorax; recovery; remarks (under the care of Mr. W. H. Battle, 218—A case of carcinoma of the left kidney of unusual duration; nephrectomy; recovery; remarks (under the care of Mr. William Anderson), 1053—A case of ovarian cyst weighing over eighty pounds successfully removed from a girl under seventeen years of age (under the care of Dr. C. J. Collingworth), 1372—Carcinoma of the urethra and bladder; removal of the growth, with closure of the resulting subpubic wound, and establishment of permanent supra pubic drainage (under the care of Mr. W. H. Battle), 1512, 1582

SINGAPORE GENERAL HOSPITAL.—Strangulated diaphragmatic hernia; necropsy; remarks (under the care of Mr. A. J. McClosky), 1116

SOUTH DEVON AND EAST CORNWALL HOSPITAL.—Case of gastrotomy; removal of a mass of hair weighing 5 lb. 3 oz. from the stomach; recovery (under the care of Mr. Paul Swain), 1581

SUSSEX COUNTY HOSPITAL.—A case of perforated gastric ulcer treated by laparotomy; recovery; remarks (under the care of Mr. E. F. Jowers), 54

TORBAY HOSPITAL, TORQUAY.—Wound of knee-joint, followed by suppuration; recovery (under the care of Mr. F. T. Thistle), 345

UNIVERSITY COLLEGE HOSPITAL.—A case of tumour of the lung; remarks (under the care of Dr. G. V. Poore), 870—Thirteen cases of diphtheria treated with antitoxin; remarks (under the care of Dr. Frederick Roberts), 927—A case of strangulation of the vermiform appendix in an infant six weeks old; removal of the vermiform appendix, which was suppurating; recovery; remarks (under the care of Mr. Bilton Pollard), 1114

VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.—Acute intussusception in infants (under the care of Mr. T. P. Pick and Mr. H. F. Waterhouse), 745

WESTMINSTER HOSPITAL.—Addison's disease of very rapid course; remarks (under the care of Dr. Donkin), 223—Notes of three cases of hernia of an exceptional nature (under the care of Mr. W. G. Spencer), 1182

LIST OF ILLUSTRATIONS.

COLOURED.

- Specimen of Abdominal Aneurysm, treated by Laparotomy and the Introduction of Wire into the Sac, accompanying description of the case by Professor W. F. Stevenson, 22
- Illustrations accompanying an Address on Evidence and the Value of Facts (Mr. J. B. Sutton), 13-16
- Diagrams showing the Distribution of Cutaneous Hyperæsthesia and Herpes Zoster in cases of Heart Pain and Sensory Disorders associated with Heart Failure (Dr. J. Mackenzie), 17-21
- Abnormality of the Chorda Tympani (Mr. R. Lake), 28
- Diagrams illustrating a case of Cystic Bronchocele (Mr. H. Morris), 29
- Illustrations of a case of Anorexia Nervosa (Mr. L. Stephens), 32
- The Narcotising Glass Mask (Dr. William Vajna of Budapest), 39
- The "Reliance" Clinical Thermometer, 39
- Illustrations of the Welsbach Gas Burner, accompanying the Report of THE LANCET Special Analytical and Sanitary Commission on the Incandescent System of Gas Lighting, 51-2
- Insanitary Premises in Budapest, 57
- Cylinder containing Liquid Sulphuretted Hydrogen, 101
- Photographic facsimile of MS. memoranda by Dr. William Harvey, accompanying address on Hemiplegia (Dr. N. Moore), 136
- Sporozoa of Variola and Vaccinia (Mr. J. J. Clarke), 140
- Diagrams accompanying Note on the Localisation of Tactile Impressions in the Brain (Dr. H. C. Spitzka), 141-2
- An Apparatus to assist in the Administration of the Bath (Dr. G. C. Stephen), 161
- Diagram showing the application of Eschmarch's Tourniquet in cases of Amputation at the Hip-joint (Mr. F. T. Paul), 215
- The Toes in a case of Ainhum (Mr. A. H. B. Hine), 218
- Illustrations of an Artificial Ear (Mr. H. N. Grove), 232
- A Tap Regulator for Gas Fires, 295
- Illustrations of a case of Myositis Ossificans (Mr. S. Paget), 340
- Engravings of Feet spontaneously amputated in Raynaud's Disease (Mr. J. Harold), 342
- A Modification of the Bivalved Speculum (Mr. F. B. Jessett), 352
- The Rhema Rack, 352
- Diagrams accompanying description of a case of Pyloroplasty (Mr. R. Morison), 395
- Gaiter Support for Flatfoot and Talipes Valgus (Mr. W. J. Penny), 417
- A New Transfusion Apparatus (Dr. L. T. G. Carré), 417
- Portrait of the late John Whitaker Hnlke, President of the Royal College of Surgeons of England, 510
- Microscope Fields illustrating Lectures on Traumatic Infection (Professor O. B. Lockwood), 525-30, 598-604, 729-35
- Pulse Tracings accompanying article on the Presystolic Apex Murmur of Aortic Regurgitation (Dr. T. Fisher), 608
- The "Compactum" Midwifery Bag, 623
- Pill Box Shoot, 623
- Portrait of the late Sir W. S. Savory, Bart., 648
- Illustrations accompanying article on the Removal of Sarcoma of the Brain (Professor G. E. Murray and Mr. W. G. Richardson), 668
- Portrait of the late Dr. D. H. Tuke, 718
- Diagrams illustrating a Study on the Treatment of Non-malignant Stricture of the Pylorus (Professor A. Ogston), 740-1
- New Dental Forceps (Mr. J. S. Sewill), 757
- Engravings illustrating Lectures on the Testes (Professor J. Griffiths), 791-8, 917-20
- Illustrations of an Operation suggested for some cases of Intussusception (Mr. F. T. Paul), 800
- The Globe Nebulizer, 817
- An Enormous Gall-stone impacted in the Ileum (Mr. W. C. E. Taylor), 863
- Temperature Diagram illustrating Note on the Relation between Dysentery and Liver Abscess (Surgeon-Major A. W. D. Leaby), 926
- A New Instrument for Exploring and Draining Cavities (Dr. G. O. Garratt), 936
- Temperature Diagrams illustrating article on Thrombosis of the Intracranial Sinuses (Dr. W. Milligan), 932-3
- Apparatus for the Sterilisation of Milk (Dr. A. H. Carter), 985
- Engraving of a case of Molluscum Fibrosum (Mr. F. K. Green), 986
- Engraving of a specimen of Idiopathic Rupture of the Heart (Mr. D. W. Collings), 987
- Clinical Diagrams for recording cases of Heart Disease (Dr. G. Herschell), 994
- An Improved Clinical Thermometer, 995
- An Improved Multiple Linear Scarifier (Dr. G. S. Taylor), 996
- Engraving accompanying a case of Pin-swallowing (Dr. J. Tily), 1052
- A Support for the Knee-joint, 1065
- Diagrams illustrating article entitled "Apologia pro Electricitate sua" (Dr. W. S. Hedley), 1108-8
- Diagrams illustrating description of a case of Hepatic Abscess followed by Amœbic Dysentery (Dr. J. Curnow), 1109-10
- A case of Pulsating Exophthalmos (Dr. A. Bronner), 1113
- A New Form of Uterine Dilator (Mr. G. A. Hawkins-Ambler), 1122
- Plan of the City Hospital, Birmingham, 1138
- Diagrams accompanying Lecture on Two Cases in which a Doubled Second Sound was audible only near the Apex of the Heart (Dr. A. E. Sansom), 1165-7
- Premises occupied by an Unqualified Practitioner, 1209
- Portrait of the late Professor Carl Ludwig, 1223
- Microscope Field showing Section of an Adenomatous Polypus (Mr. C. A. Morton), 1246
- Diagram accompanying Lecture on the Relation between the Movements of the Eyes and the Movements of the Head (Professor A. C. Brown), 1296
- Temperature Chart accompanying article on Malarial Fever in Warri, West Africa (Mr. F. N. Roth), 1304
- Illustrations of a case of Necrosis of the Tibia (Mr. W. H. Brown), 1310
- Celluloid Vaginal Douche (Mr. R. H. Rains), 1321
- A Simple Urethrotome or Urethral Knife, 1381
- Illustration accompanying description of a case of Congenital Dilatation of both Ureters, 1436
- The Yale Surgeon's Chair and the Gould Dental Chair, 1441
- Diagram illustrating Diphtheria Mortality in London in 1894, 1456
- Illustrations accompanying description of Turbinal Varix, 1501-3
- Mass of Hair removed from the Stomach, 1581
- The "Aria" Patent Safety Lamp, 1585
- Portrait of the late Sir G. H. Porter, Bart., 1613
- Diagrams illustrating the Micro-organism of Cancer (Dr. J. Braithwaite), 1636, 1637
- Illustration accompanying the Description of an Operation for Webbed Fingers (Mr. Leonard A. Bidwell), 1641
- A new Portable Secondary Battery, 1648

END OF THE FIRST VOLUME FOR 1895.

Published by the Proprietors, at No. 43, Strand, and Nos. 1 and 2, Bedford-street, Strand, in the Parish of St. Martin-in-the-Fields, London.-Saturday, June 29th, 1895.

In Introductory Lecture

UPON

THE TYPES OF STUDENTS.

*Delivered at the opening of University College, Session 1863-64,
and Reprinted from THE LANCET of October 3rd, 1863.*

BY SIR J. RUSSELL REYNOLDS, BART.,
M.D., F.R.C.P. LOND., F.R.S.,

NOW PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON;
EMERITUS PROFESSOR OF MEDICINE IN UNIVERSITY COLLEGE;
AND CONSULTING PHYSICIAN TO UNIVERSITY
COLLEGE HOSPITAL.

THEN SPECIAL PROFESSOR OF CLINICAL MEDICINE IN UNIVERSITY
COLLEGE; AND PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

GENTLEMEN,—The office of "Special Professor of Clinical Medicine," which it is my honour to hold in University College, has furnished me with opportunities for the study, not only of patients, but of students; and I purpose to-day to present you with some of the results of those clinical observations which I have made upon the latter.

The term "clinical lecture" is often applied to a discourse delivered elsewhere than at the bedside of a patient. In like manner a familiar phrase is often used to denote a species of exhortation, or it may be rebuke, administered at other times than in the hush of night, and under circumstances of less privacy than the "curtain" might secure. If, then, I denominate the remarks I am about to make "a clinical lecture upon students," common professional usage of words will be on my side, if strict etymology is not; for those remarks, although delivered in the theatre, are founded upon observations conducted, for the most part, in the wards. And if anything I may say should seem to have the tone of exhortation or rebuke I wish you to think that such message comes to you from the other side of the curtain, where lies the patient, not any individual patient, but the great suffering world, which is at once our study and our care.

It is towards clinical work that all medical study tends; it is at the bedside of the patient that our "science" culminates, and becomes an "art." The "case" with which we come in contact is, as it were, the "medium" through which "correlated forces" become exchanged; or, to alter the figure, the "reflective centre," in which all the "knowledge" we have laboriously gathered from without becomes converted into "power" for the patient's good. It is well, therefore, to keep this end in view, and to regard all our studies in this their high relation. The bedside of the patient is the point from which to value correctly all scientific medicine; and it is from this standpoint that I would now address you. And in delivering a clinical lecture upon students I shall not depart from the plan I usually adopt, but shall commence by giving you a picture of the cases that I wish to bring before you—they are five in number. After having described them, I shall advance to a consideration of their pathology; but, first, let me sketch these cases as you may have seen them, and may again see them, in our wards.

CASE 1.—Cyrus Vane Velox is between nineteen and twenty-four years of age. His last year or two have been nominally spent at the College. It was observed while he was there that his attendance upon lectures often assumed a remittent form; that occasionally prolonged intermissions occurred; that the intervals between his paroxysms of attendance gradually increased in length, and that some curious repulsive influence seemed to become developed, not only between himself and the lecture-room, but between himself and the professor; for it was noticed that upon each period of his return he withdrew himself further and further from the professor's position in the lecture-room or the theatre. At first he sat in the lowermost rows of seats, and occasionally took notes of the lectures that were delivered; but afterwards, having eaten his pens, he was reduced to the necessity of making such notes and illustrations as he could with his penknife on the surface of the benches. A disadvantage attached to this process was that he could not carry these notes away for private use; but he succeeded in taking his notebook away, and it was subsequently ascertained to have passed gradually from the desk to his pocket, from his pocket

to his locker, and he appeared quite devoid of it after a little time, having substituted for it a walking-stick, the proximal extremity of which he usually kept in his mouth as he sat at the top row of the theatre, or removed it from that locality only to make slightly audible rhythmic movements upon the floor. Another fact noticed about him was that the commencement of his attendance upon individual lectures became gradually delayed; so that on one week it was five minutes past the hour before he arrived, the next week ten minutes, and so on until he disappeared altogether. A curious infirmity affected him in the dissecting-room. He was usually seen seated between his "upper" and his "Ellis," as unhappy as if he were about to be dissected himself; and looking abjectly into mid air, as if he expected that anatomical knowledge might by some strange occult projection penetrate his own "head and neck," and perchance remain there. But instead of this happy result he soon verified in his own experience the old anatomical and physiological discovery that there is a passage by which truth that has entered in at one ear may very readily pass out at the other. And so, instead of "cleaning the muscles" he cleaned his scalpels, cut up his "part," or allowed someone to do it for him, and promised to himself to "get up his anatomy" at some time or another by the aid of one of those rotatory machines which must be nameless.

Having thus finished at the College, he came across to the hospital, and was admitted. A delay appeared to attend his admission, and in a chronic form, it affects him still. It takes him generally from ten to twenty minutes to get through the lobby of the hospital, and he has been known sometimes, so great is the obstruction, to get no further. A casual observer might think he was not trying to effect the passage, as he often seems to be standing with his face to the street, conversing with others afflicted like himself, and producing severe "portal congestion" of the institution; or sometimes talking even to the out-patients as they pass the door into their waiting-room; but his conversation has not, so far as I have observed, been directed to the discovery of their diseases, his principle of selection amongst these out-patients, who are rarely if ever of the male sex, appearing to be rather closely associated with the presence of good looks and the not very conspicuous presence of modesty. The stick with which he broke out a year and a half ago is still visible, there is often a want of correspondence between the vertical line of his body and the median line of his hat, and the detrusion of the latter towards one or the other side has of late shown a marked tendency to increase. This little symptom has been observed a great many times, and its exacerbation has been thoroughly established. There can be no doubt of the correctness of the observation, for our patient usually keeps on this appendage of his when others are in the habit of removing theirs. After, however, the considerable delay occasioned in the manner I have described, our case arrives in Ward III., and the "present state," as entered in my notebook, is as follows:—

C. V. V.—, found sitting, with his hat on, upon the corner of the table in the middle of the ward; thus, during the early part of the visit, maintaining as great a distance as he conveniently can between himself and the patient first examined. Moving gradually towards the fireplace, he places his back opposite that calorifying arrangement, so that he can take a comprehensive view of the ward by seeing all the patients it contains at one glance. He yawns frequently, comes into the outermost circle of students around the bed, looks first over the shoulders and then under the axillae of those in front of him, fails to see anything of the case under examination, and so talks and jokes with his nearest neighbour, not loudly, but in a tone which does not materially assist those who are commencing the practice of auscultation. He walks to a distant bed, looks knowingly at the bed-card, sees the patient's name, age, and occupation; makes his diagnosis by reading that which is written on the card; judges of the treatment by smelling the bottle of physic; is thus able to say there is a case of rheumatic fever in Ward III.; and having ascertained that important fact, he seizes an opportunity, when the physician appears to be looking the other way, and rather quietly—out of consideration, let us now hope, for those who are listening to cardiac murmurs—he takes his leave. The periods of his return to the wards are singularly uncertain; but it has been observed that they bear some curious relation to lunar time, and that they are often synchronous with the recurrence of those days on which the names of students have to be entered in the book kept near the door. It was most mercifully arranged that this book should be kept so near the outer door, for the fatigue occasioned by effecting the passage

generally. He competed for honours in the classes of Anatomy and Physiology, but obtained only very low certificates; while of course he gained, as everyone knew he would do, the gold medal in the class of Chemistry, and his papers were such as have seldom been presented by any student of the College.

At length he came over to the hospital for clinical study. His honours at once secured for him the office of clinical clerk, and here he had many opportunities for considerable chemical research. He ingeniously managed always to secure for himself those cases in which some special interest attached to the examination of the secretions, and these he noted with a carefulness that did him the highest credit. But it may be observed, now that his clerkship is completed and he is pursuing his own way in the wards, that he often passes over some of the most important features of a case in order that he may be quite accurate about some, as yet understood, unimportant detail. It is said that C. P. could tell you correctly all the daily changes in the urine of each case of pneumonia, chorea, and gout that has presented itself during the last twelve months; but that he would be puzzled to distinguish a case of pneumonia from one of bronchitis, and that there are many forms of disease of which he scarcely knows the names. A relative of C. P., who was in the hospital some years ago, exhibited a similar affection, but it took another form; and the result in him was that he was thoroughly *an fait* in all chest diseases; his ear was tuned to the detection of the very finest departures from healthy sound; "he knew," as his fellow students used to say, "his Walshe by heart"; but he was sorely perplexed to make a diagnosis when examined for the office of physician's assistant. Indeed, the case was one that baffled him completely. He made out the presence of sonorous chonchi in the chest; he was confident that he heard some fine crepitation at the junction of the middle and lower thirds of the posterior surface of the left lung—the resonance was defective there; and he occasionally caught, as it were, the dubious ghost of some grazing friction. On these points he was as clear as noonday; but he failed to see that the patient was suffering from measles.

The last class of cases that I wish to bring before you is, I am glad to say, far from uncommon in our hospital. Perfect examples we do not expect to find often; it is rare for any case to resemble exactly that which is described in books. Nature does not move in the narrow ruts or lines along which our thought seems, as it were, compelled to travel. But again I say it is useful to consider types; and—

CASE 4.—Orbicularis Goodman is a fair type of the class to which he belongs. His brother—(Case 5) Longitudinalis—is here also. Their family and early history is the same; they are very much alike. I shall point out their differences as I proceed. Both brothers diligently attended to their college duties, having prepared themselves to enter upon these studies by some acquaintance with general physics and with those laws of thought which regulate all forms of scientific inquiry. They studied equally each branch of knowledge; became competent, by their acquaintance with anatomy, physiology, and chemistry, to comprehend the principles of morbid change in both function and structure of the body; they attended lectures, when professing to attend them, with punctuality and regularity; but they did not waste time by going uselessly over the same ground again and again. They did not lose the continuous thread of information which a course of lectures can supply; but having gained that they used other means to confirm and enlarge their knowledge. They asked themselves and others, before commencing the study of a subject, what it was that they were about to learn. They acquired, as it is most important to acquire, some knowledge of the subject to be known; and thus they understood what it was they wanted to learn when they came to the hospital to use their own eyes, hands, and ears in the observation of disease. In their clinical work it may be seen that they follow this general plan. They attend for a time the practice of one physician or surgeon, and then for a time that of another. They pay special attention to four or six cases, endeavouring to select those which are examples of the same or of allied diseases; they compare them with each other; they compare them with written descriptions of such diseases; they endeavour to make out the causes of symptoms and their relations with one another; they hear what is said about them by the physicians and surgeons; they take time in their examinations, and go to see these cases in the morning as well as at the hour of visit; they master each

case, and keep a careful record of it; they do not try too much at once; they endeavour to know thoroughly what they know at all; they are not afraid to ask questions; and they are very successful in the advance, not only of their knowledge, but of their power to know. There is this difference between them: the elder appears satisfied when he finds a case that corresponds exactly with a book; the younger is always trying to show his brother that the book is wrong. The one is disposed sometimes to fit his facts to the ideas he entertains of what facts ought to be and to strain them a little, sometimes this way, sometimes that, in order to make the fit complete and creditable; the other is so averse to believe that facts ever do correspond with statements that he sometimes looks at them through a distorting medium, and imagines that there are exceptions when there are only blank spaces or wrong entries in his own information. The elder sees things that do not exist; the younger as often fails to see those that do. The one is ever trying to verify the wisdom of the past, the other to show that it fails to meet the knowledge of the present; while the former looks somewhat hopelessly at the future of our science, the latter believes that it will witness the solution of every enigma, the unravelling of every tangled skein of truth. The two brothers, while they counteract, yet supplement each other, and help each other onwards in the pursuit of their common end, the acquirement of all that knowledge which, however imperfect it now may be, is yet the best that can at this time be brought to bear upon the sufferings and sorrows of their fellow men.

The outside phenomena of five groups of cases have now been brought before you; and in order to advance to a knowledge of their pathology I wish to point out the primary or essential fact in the departure of each from healthy action. This may often be found in the *absences* of some important principle or quality. Look at the first example, and see how certain defects disqualify him for the work he professes to have undertaken. He fails to see the greatness of that work. By his presence here it is assumed that he wishes to learn the science and art of medicine—i.e., to know all that can be known of the most complicated set of phenomena that can be studied by the human mind. He requires patience and untiring energy, but he exhibits neither. He fails to see the value of his time. He cannot hereafter make up for the opportunities he is now daily allowing to escape unimproved. There is a want of consideration, a want of common sense, in a man's undertaking a work of great magnitude and treating it as if it were mere child's play. Lives have been spent by some of the greatest intelligences of our race in acquiring and arranging the knowledge with which he ought to become familiar; and that man's intellect is defective who professes to study medicine and who takes no pains to do it. To attend lectures with irregularity, and to saunter lazily through wards filled with patients who might teach him what he professes to want to know, proves, I submit, a want of intelligence in the first case I have described; but, further, there is a want of honesty and want of heart. C. V.'s father lives in the country, and leads a laborious life. He is in constant and wearisome attendance upon the sick poor of a large union, or he is hurried from house to house to hear the oft-told tale of suffering and weakness—of miseries made tenfold worse by want. He spends the long hours of a winter's night in some wretched hovel, where the sorrows of a woman, because her hour has come, find no turning into joy that a man is born into a world so dark as hers. He has closed the dim eyes of some old labourer whose day of toil is done. The great mysteries of life and death surround him; he stands alone in his struggle with the sorrow and the suffering that beset him on every side; he has no colleague to cheer him in his work or to help his own wearied brain; all that he does is without the *relat* of public position or the reward of fame. His family is large and his means are small; his wife performs household duties to which some fine servants would object; his daughters have but short school days, and then have to give out to others the little they have learned. It is all hard work in young Vane's home. And why? The father labours that his son may learn: he has placed him here amongst immense advantages; his small savings scarcely meet the hospital and college fees; but yet, while there is stint and toil at home, he saunters lazily about the wards and lecture-rooms, and never lightens, by the effort of one little finger, the great burden some part of which his broad young shoulders should have now learned to bear. There is want of common

honesty in this, and want of heart; and this last he shows quite frightfully sometimes when he makes his visit to our wards. Let him not stare rudely at the patient just come in. Let him, if he will, handle, but handle tenderly, the palsied arm that has done much work when once it was strong as his. Let him not choose the wards for a rendezvous in which to chat idly with his friends about the boat race or the billiard match; but let him come with reverence and with uncovered head into the presence of disease or death, and feel that sorrow and suffering demand a respect which it is his honour and duty, as well as his privilege, to pay.

Leaving now the first case, the prognosis of which is by no means good, I wish to analyse the second much more hopeful specimen of student life represented by Superficialis Hurry, whom you will remember we found always in haste, and most ubiquitous in the distribution of himself. Praiseworthy as his energy is, he makes a vast accumulation of material which is of little use to him by reason of the confusion in which he leaves it. He has seized a fact here and another there, but he has not been able to bind them together. He often so learns the answers to a number of questions that he is "safe to pass an examination" if he is only fortunate enough to get the proper questions; but there are facts which lie between those questions and which throw light upon their answers, and these he has hitherto failed to see. The scraps of knowledge he has gathered are to him something like "cut flowers" standing in damp sand—varied and beautiful to look at, even doing something with the life that lingers in them but is quickly vanishing away; whereas they should be living things, firmly rooted in the earth they spring from; transforming crude into less crude material; raising the lower forms of matter into higher; assimilating much that is heterogeneous, and evolving new products as the result of their own inner life. What D. S. H. fails to perceive is the existence of a deep-seated relation between all the facts that come before him; that they are, as it were, twined together by their roots; that they have a common holding to the earth they spring from, and that he must dig deeply who would learn their meaning; that underneath the surface phenomena he has scanned so slightly there are relations which cannot sometimes be seen or handled, but which may be appreciated if he would fully comprehend the phenomena he has witnessed. The manifold facts he has to learn and use resemble rather a mighty forest, with trees of an age's growth, whose brawny arms have other work to do than to bear upwards their own leaves, and thus nourish their own life; for on them the ivy clings and plays its part, and their bark is stained by the busy lichen or is fringed by moss; while under their shade, and protected by their care, flowers of a thousand hues give forth their scent, for a few hours wave their fragile petals in the air, finish the work that is given them to do, and then pass away: where life in all its forms is moving with restless energy, and moving towards the accomplishment of one great end; where the roar of the beast of the forest not only does his bidding, but, as it shakes the dew-drops from the gossamer, drowns a whole colony in that tiny flood, and so feeds the dawning life we fail to see; where the insect in its search for food scatters the pollen from the anther, and thus helps to renew the form it lived upon; where life in its thousand forms finds its great bonds of union and transformation in the earth and air; the roots deep down in earth seeking and finding in the darkness, amid crumbled rocks and the ruins of past forest life, the very elements they need; the earth drinking in the rain that, as it falls through air, brings back again those seen and unseen fruits of their toil that the great live world above has filled it with; and over all the sky, with its marvellous, mysterious agency of light and heat, returning to all living things the powers that first called them forth or roused them to their toil. In Nature there is a wondrous unity of advancing purpose amid a vast circle of events; no link can be dropped from her mighty chain; nothing can be added thereto, nothing taken away. She is before us for patient and reverent investigation, and he will never learn "her secret meaning in her deeds" who is content with a hasty glance at the first facts that come to hand. No, he must trace each fact into its past and future; he must see how it came where it is, how it lives, and how it grows. He must follow the teaching, which Nature herself is ever ready to afford, that nothing is small, that nothing stands alone, that in darkness and "in silence mighty things are wrought," and that what we see is but the outcome of still greater things and forces as yet

unseen. He must, then, work widely and work hard, but he must work deeply too, and in so doing his progress must be slow. He may, and will, find his knowledge less showy, but more real; it may even be thought less of by some around him, but it will be of far higher value to himself.

There is a caution, with regard to clinical study especially, which I would give to all who are in any degree affected with the malady of Hurry. It is that they should never allow themselves to sacrifice accuracy and thoroughness of information at the shrine of definiteness. There is something very charming, very easy to remember, in broad lines of distinction, and such lines are often highly useful; but they rarely go down to the bottom of a matter, and are often on the barest surface only. It may be enough, in order to enable you to distinguish between two particular individuals, to say that one wears a violent Albert chain and the other a broad-brimmed hat; but such characteristics do not by any means exhaust the differences between a dandy and a Quaker; and if they were taken to do so your generalisation might be broken to pieces by the experience of to-morrow. There are diseases which may sometimes be distinguished from others by the presence of one symptom: value it, but value it correctly; and remember that in every case you have a whole body for your study. And do not rest satisfied with applying some little fragments of your science to the mere fragments of a case; but bring all your knowledge to the interpretation of every case, and depend upon it you will not often find that you have one grain too much.

Now, let us see wherein it is that our *third*, painstaking student—our devotee of chemistry—is at fault. He has worked well at his favourite study; he has partially, but not utterly, neglected other portions of the full curriculum of education. Unlike D. S. H., he recognises the importance of digging deeply in his work, but practically this deep digging is carried out only around his own favoured plant. He will examine its tiniest root-radicles, and the bristles upon its most distant leaves. He knows all its aspects, and has recorded with praiseworthy care every detail of its growth and change. But of other plants he knows but little; and he feels almost an approximation to contempt for those who do not move along the line that he has chosen. He recognises the marvellous interdependence of all Nature's works, and the analogous relation between all branches of science. He sees that "physical" science, to be complete, must embrace those properties of matter which have to do with the "proportion" in which one kind of substance combines with another; that the idea which we form of an "elementary body" is based upon the possession by that body of a certain group of physical qualities differing from those which are presented by another; and thus that physics and chemistry are not distinct sciences, but parts of one comprehensive view of the substances by which we are surrounded. Further, he sees that, in order to understand all these properties of matter, he must trace out their behaviour, not only in the so-called inorganic but in the organic world; and that a full natural history of any element cannot be said to be written until its presence and effects are known in both the vegetable and animal kingdoms; and yet further, that the knowledge of these must embrace not only the processes of health and growth, but those of disease and decay. Thus he is right in holding that all our science is but one great science, and that the lines which we have found it convenient to draw between this branch and that of the great sum of knowledge are always artificial and often wrong; that all systems of classification—whether so-called "natural" or not—are but human systems, tinged by error and dwarfed by ignorance; that the only really natural distinctions are those which Nature herself presents—viz., the distinction of individual from individual and of element from element; but that we are as yet by no means certain that we have absolutely accurate tests for the recognition even of these, as it were, final or primary distinctions. In perceiving them, however, we come face to face with Truth. When we attempt to advance further, all that we do is to gain glimpses of a mighty order that we fail to grasp; the arrangements we adopt follow the leadings of our own but partially instructed minds; and in all the statements that we can frame about them we of necessity introduce the elements of incomplete observation and of imperfect thought. But what C. P. fails to appreciate duly are the greatness and many-sidedness of Nature's works, and also the present imperfection of our means for knowing them. True, an absolutely perfect science of Chemistry must embrace all knowledge; an absolutely perfect Physiology

must do the same. But we are far from having attained to these, and cannot reach our goal by starting from one point and advancing through one avenue alone. Dealing with so complicated a phenomenon as Life, we must approach it from many points: we must start from the side of "Physics," and also from that of "Chemistry"; we must advance also from those, as yet unreduced, "Vital" processes, and again from those of our own "Consciousness" and from the facts of "History." We cannot yet see the point in which all these converging lines may meet; but in the meantime, believing that they do meet, we must work and travel, not on one line alone, but upon each and all, and so approximate the knowledge we may even at the last fall fully to possess. Work, then, as deeply as you can, but look around you also. Do not neglect a fact because it stands, as it would seem, apart, or because it is of some order that differs from your own favourite study; do not think it worthless because you cannot verify it in one particular way, but learn to verify it in another: gain all the knowledge that you can from all sources, and bring it all to the interpretation of any phenomenon or process that you are endeavouring to understand. There are many life-processes that cannot be estimated by the thermometer or the scales; and they have a value of their own. The manner of respiration will often teach you more than the number of inspirations in a minute; the quality of a pulse will often give you more insight into a case than will its frequency; an expression of countenance will, not rarely, teach you more than a chemical examination of secretions.

The last cases (the fourth and fifth) which I brought before you were those in which time and labour were well spent, and would inevitably bring their reward. Before they commenced medical study the two brothers Goodman knew something of physical and mental science. Preliminary education cannot well have its advantages exaggerated, but I am far from thinking that feats of mental gymnastics in respect of classic lore have any direct influence on the success of a student of medicine. He must be "in good condition" mentally, and no man gets into that good condition without some "training." A part of this training is the study of the languages and literature of the past; but for its immediate influence upon his scientific career it is of more importance that the student should be familiar with modern languages, and especially with French and German. It is, however, of essential importance that he should be well versed in the physical sciences. No man can make much of anatomy, chemistry, or physiology unless he knows something definitely and scientifically of the great laws of matter. The fact of having studied these, of having learned the mode in which they are to be investigated, and the nature of the processes by which hypotheses are to be verified or refuted, will place him on vantage-ground in his studies here. He will understand what is the value of a "fact," what is the nature of a "law," and what is necessary in order to regard the one as proved, the other as established. And almost inseparable from a knowledge of physical science is an acquaintance with the nature and order of those processes of mind which are common to all kinds of philosophical investigation, which the child or the savage may apply with instinctive correctness, but which the man of science will use but ineffectively unless he has arranged and analysed them. I do not think that the medical student will be any the better qualified for his work by having his brain filled with metaphysical questionings or ontological speculations; but I am quite sure that a systematically arranged knowledge of the greater and simpler laws of reasoning and of thought will enable him to appreciate much more readily than he could without such knowledge the wide range of phenomena which will come before him here. Thus armed and fortified, the two brothers commenced their attendance upon lectures in this College; and they made, in the manner I described, appropriate use of those great advantages. I cannot but regard them as such, although some in the present day speak of lectures as though they were remnants of an antique species of torture, fit only for exhibition in the Tower of London, with waxwork models of our learned professors, as specimens of a crude state of education now happily extinct. But I think that the lecture has powers for good which nothing yet devised can supplant. The book brings the whole mass of information before you at once; the lecturer gives you day by day the proportion you may take in and assimilate. The book is a dead thing—a moveless, emotionless conglomeration of words, which you may stare at and try to comprehend, but which cannot see or feel your

difficulty, cannot change its phrases, and cannot fill up those gaps in your knowledge which prevent your appreciation of its meaning. In the teacher you come in contact with a living man, who sees whether you do or do not comprehend his teaching; who can use simpler forms of speech, and by some trifling change of words make quite clear to you what before was dark as night; who can see where the links are missing in your chain of thought, and can supply them; and who can thus fit you for the work of self-teaching, which, to those who have learned something, is the most valuable of all.

The two brothers I have described, though agreeing in their earnest and successful work, differ in scientific method. The elder tests "observation" by "authority," and finds it wrong; the younger weighs "statements" against "facts," and finds them wanting. The one regards with all his affection, and seeks for with all his energy, the establishment of the uniformity of Nature's processes; the other as earnestly endeavours in those processes to discover, advance, or progress. What the scientific worker really needs are an appreciation and combination of the two; for in nature they are both present, and we may and do observe them both. Look at individual life, and see that some great processes go on in the same way from hour to hour, from year to year. There is the alternate diastole and systole of heart; the constant play of inspiration and expiration, with their effects on air, and blood, and tissue; there is the daily change from sleep to waking, from activity to rest; there is the daily disintegration of tissue, the excretion of waste material, and also the daily assumption and assimilation of fresh supplies. Further, there are recurrences, with wondrous order, of some physical changes—partly those of health, partly those of disease—at still longer, but yet time-ordered periods, and the seasons of this year have effects like to those of the years that have gone before. But with all this order, and as the result of this order, there is progress: the infant grows into the child, the child into the youth, the youth into the man. The changes of dentition and of puberty lead onwards to the full growth of the adult; and then, in its due time, decay comes surely on. Some diseases may appear, go through their well-known phases; observe periods that we can with certainty predict; but they have not been in that individual before, and they will not visit him again: they have done their work. All that he has passed through makes him what he now is; there have been recurrence and order, but also growth that does not return into itself. Yet look further, and see that this growth has its order also: lose the individual in the many, and then see that those things which occur in him but once, which even constitute his separate life, do recur, but recur in others; and so again we see the circle, but a wider one. But is there no progress of this larger group? Look at families, at races, at nations, and you may see that they, too, have their periods of infancy, of youthful follies, of angry passions, of wise discretion, of luxurious ease, of creeping feebleness, and dusty death; and while the one nation, with its one life, sinks away, another takes its place, and the great world is ever young. But the great world also grows, and—

"I doubt not through the ages one increasing purpose runs.
And the thoughts of men are widened by the process of the suns."

Look at our sciences from another point of view. See how in that of physiology, in its larger aspects, we observe an onward progress amidst the orderly recurrence of events. Not merely individuals but species become extinct; new species take their empty places, and lower give way to higher forms of life. Whatever may be the theory for its explanation, there can be no doubt about the fact that the life upon the world at this present moment has not the form it had; seeming uniformity of process has wrought out change, and that change is one of progress or advance. We do not exhaust the question of how this is, we only move it a few steps further backwards, if we admit the principle as readily as we see the facts of so-called "natural selection." Go back to the simpler types of life; imagine, if you will, that all the variety that now clothes the world has sprung from one common form; you must then admit that there was in it the possibility of divergence from the type, or, in other words, that it contained within itself the germ of all subsequent developments; and thus, in the only conception we can frame of primeval life, we see in its apparently simpler but really more complex order the mainspring of advance. We observe the same combination if we regard at an early period of its development the now living individual or species. It

is easy enough to trace life backwards until we fail to see the differences that lie hidden in some foetal form, common to all kinds of fowl, to the donkey and the dog, to the monkey and the man. But do not let us suppose that differences, though hidden, do not exist. We may not be able to distinguish the one ovum from the other, and yet the difference between them is so great that one becomes the peacock and the other the Cochín-China hen; the one a Skye terrier and the other a learned Doctor of the Law. It is when brought face to face with facts like these that human science, grateful for what it is, should not trumpet forth generalisations to which it has leaped, to conceal its weakness, but should show its real strength in humbling itself before great truths that are as yet past its finding out.

Again, in the yet infant science of geology we may observe the same combination. We argue upon the supposition that the processes of past times were like those of to-day; we believe in the constancy of the operation of Nature's laws. But yet the result of all this is that the world's face has changed, and is changing still; that while the earth lasts, although heat and cold, summer and winter, never fail, they never fail to do their work, and that that work does not, so far as we can see, return into itself, but carries out some mighty plan, the mere alphabet of which we have as yet been able to learn.

Notice once more how both order and progress may be seen combined in the history of scientific systems and of philosophic method. Their movement is onward, but it often appears to return into itself; yet it does not thus return. It is not a circle that is described, but rather, as it has been said, a widening and ascending spiral, whose ultimate course we cannot now compute.

Lastly, see how in human life the one kind of law, by its constant and orderly operation, develops results of another and a higher kind. See how the physical forces are often determined in the direction of their action by the chemical constitution of the bodies in which they are displayed; how chemical actions are co-ordinated to produce results which cannot be expressed by chemistry alone, but require another set of terms, which we denominate the vital; how animal life is determined by mental conditions; how the latter often yield to social and moral obligations; and how marvellously they are all intertwined to produce that complex creation—a living man. How long the apparent conflict of these two elements will last in science we cannot tell. Where is their common point we cannot see; but as the circles of order widen they lose their apparent recurrence, and order and progress become, even in our own minds, one. The infinite circle is identical with the straight line infinitely produced. Our definitions fail, or contradict themselves, when we endeavour to carry them thus far; but we feel confident that there is no contradiction in the things themselves, and our finite minds can feel assured of the existence of some great facts that they have as yet failed to grasp, and may be convinced of the reality of an infinite, abiding, and eternal Truth in which all truths shall centre; in which is no error—no darkness at all, but which can now be only dimly seen or felt after amid the changing and passing shadows of time.

In entering upon our profession, then, you must take high views of its vast demands as a science and of its claims, not only upon your mental, but upon your moral nature. Avoiding carefully the errors I first described, see to it that you have untiring industry, but that your work is deep as well as broad. Strive to learn the inner, often-hidden relations of all branches of your knowledge, but remember that much is yet hidden, and that, therefore, you must approach truth from many sides. And, lastly, in your earnest work to know the laws of life, and in your hereafter daily contact with life—at its beginning, in its troubles, and at its close—do not, in recognising the divinely appointed order of all events, lose sight of that great divine plan of progress which will surely evolve the highest good out of much that now seems deepest evil. You will thus often see a moral purpose in the suffering you try—but try vainly—to assuage; a good in the death you feebly struggle to postpone. Regarding disease as fraught with meaning and purpose other and higher than the mere change of organ you can see and handle and record in your pathological note-book; looking on death as the fulfilling of some greater end than can be represented in the Registrar-General's returns; though often saddened, often baffled in your unequal conflict with these two great foes, you may see that they also have a work to do, perhaps more friendly than your own; and thus

you will be led to feel, and that with a conviction no other profession could urge so strongly upon you, that though—

"Suffering is permanent, obscure, and dark,
And has the nature of Infinity.
Yet through that darkness (infinite though it seem
And irremovable) gracious openings lie,
By which the soul—with patient steps of thought,
Now toiling, waited now on wings of prayer—
May pass in hope, and though from mortal bonds
Yet undelivered, rise with sure ascent
Even to the fountain-head of peace divine."

A Clinical Lecture

OR

CASES OF PHLEGMON AND ABSCESS INVOLVING THE ABDOMINAL WALLS.

*Delivered at the Middlesex Hospital during the Winter
Session, 1893,*

By J. W. HULKE, F.R.C.S. ENG., F.R.S.,

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; SURGEON
TO THE MIDDLESEX HOSPITAL; CONSULTING SURGEON TO THE
ROYAL LONDON OPHTHALMIC HOSPITAL, ETC.

GENTLEMEN,—The cases to a review of which I invite your attention to-day are instances of phlegmon and abscess involving the abdominal wall. When we consider the large extent of the abdominal parietes, how exposed they are to external violence, and how extensive are their anatomical connexions, the large amount of subcutaneous, paramuscular, and subserous connective substance comprised in them, and the large quantity of fat this usually contains, it may, perhaps, to some of you appear singular that so few instances of these inflammatory disorders implicating the abdominal wall are received into our surgical wards. You will not have been many years engaged in practice before you will have found that these cases fall naturally into two groups—one comprising those cases in which the phlegmon or abscess originates in and usually continues restricted to the abdominal wall, and the other group comprising those cases where the abdominal wall is implicated in the progress of a phlegmon or abscess the focus or starting-point of which lies elsewhere—it may be near or remotely situated. The first is quite a small group, its cases are infrequent; but the second is a wider group and includes the greater number of cases you will meet with. Probably in the first group the most usual cause is mechanical violence—e.g., a blow or a severe squeeze. Such a case was the following not long ago in Bird Ward. In the case-book the patient is described as a woman aged fifty-three, a stout, heavy person with a large, fat, pendulous abdomen. She had fever, and she looked very ill. In the lower part of the front of her abdomen was an extensive red swelling without definite margin; and in the middle of this, nearly midway between the umbilicus and the pubes, was an oval patch of gangrenous integument two inches by three inches across. Along its lower border the detachment of this slough had begun, and from the narrow groove of separation between the living and the dead part oozed a thin puriform discharge, in which floated small shreds of necrosed connective tissue. She said that twelve days previously, whilst standing on a chair to wind up her clock, one leg of the chair broke through a defective place in the floor of her room, causing the chair to tilt, which threw her down, and in falling the front of her abdomen struck violently upon the top edge of the chair-back. This hurt her so much that, when those who went to her aid lifted her up, she found that she could not stand, and she was compelled to lie on her bed during several hours. However, late on the same day, with help, she managed to get to the casualty department, where she was examined and prescribed for. She continued to be seen as an out-patient during several days, when, the consequences of the injury appearing to be more grave than had at first been thought, she was made an in-patient. Here the local disorder was obviously a phlegmon. A violent blow had very severely bruised her big, hanging abdomen, not merely superficially ecchymosing it, but probably also causing an extravasation of blood in some

quantity, occasioning a hæmatoma. The patient being allowed to be up and going about her affairs, the bruised part was unavoidably subjected to pressure and to chafing by her linen, very likely not particularly clean; some minute breach of surface might have occurred, allowing the ingress of septic noxa, and this provoked inflammation of the weakened tissues, ending in their gangrene. At the time the patient was taken into Bird Ward the phlegmonous process was already arrested, the beginning detachment of the slough afforded a sufficient outlet, and all tension had ceased. The parts were lightly dusted with iodoform, and thickly sprinkled with powdered boric acid, over which was placed a compress of cotton-wool dipped in a saturated solution of boric acid and wrung nearly dry. Two days later the slough was completely separated and thrown off, leaving a sore which soon cleaned and began to cicatrize. When the sore had decreased to one-third of its original size granulation appeared to cease, and for a day or two no progress seemed to be made. Three skin grafts were therefore set. Of these, two took, and three weeks later the wound was completely and soundly closed. Had this woman been kept in bed from the time of her accident, had the bruised part been protected from further injury, had ordinary measures for asæpsis been enjoined, and had a rag dipped in Goulard lotion been applied it is likely that the swelling immediately resulting from the injury would have disappeared and the occurrence of a phlegmon have been averted. Here is another case, also one of the first group. A little boy aged four years was admitted into Percy Ward. His flushed cheeks and high temperature told of fever. In the lower part of the front of his abdomen was a conspicuous, large, prominent, red, tender, aching, swelling. This manifestly was an acute abscess. His mother said that nearly two months previously the child had been knocked down by a cab in the street. He seemed soon to recover from the shock, and she hoped that he had not been seriously hurt. He had before had excellent health, but soon after the accident he appeared to be ailing. Then she noticed the swelling, and as it increased she brought him to the hospital. The abscess was opened. About eight ounces of greenish pus with broken-down blood-clot escaped. Three weeks later the abscess cavity had closed, and appearing convalescent he was allowed to be taken home.

Here also, in the absence of symptoms pointing to other than a local origin, and with the distinct statement by the mother of the child's good health before the accident, we appear justified in assuming that the abscess arose from suppurative of a hæmatoma and in causally connecting this latter with a mechanical injury sustained when he was knocked down. Probably the hæmatoma was intermuscular, since had it been subcutaneous, ecchymosis would have soon ensued and have been noticed. If this view of the case is correct it must be regarded as fortunate that the abscess pointed externally. Perhaps this is referable to the hæmatoma having been inter-muscular and not subserous, in which latter instance the path of least resistance might have been through the peritoneum. You had not very long since in Percy Ward an opportunity of watching a case where this last presumably occurred. The patient, a little boy, was admitted with an acute inflammatory swelling in the lower half of the left side of the front of his abdomen, also the sequel of an injury sustained by his having been run over by a cab. This was obviously an acute abscess in the abdominal wall. The child's health had been good, and no symptoms indicating visceral injuries had supervened. It was intended to give him nitrous oxide gas and open the abscess, but before this was done a notable subsidence of the swelling became apparent, and soon afterwards several ounces of pus were voided through the rectum. It is certain that here the abscess in the abdominal wall had opened into the gut, probably into the sigmoid flexure of colon; and that this occurrence had been preceded by the formation of adhesions between the parietal and the visceral peritoneum, so barring off the sac of the peritoneum from contamination by the escaping pus. From the formation of a communication between the abscess cavity and the gut there arose the possibility of the entrance of fecal substances into the former; but this did not happen, and so the ill effects incidental to it were absent. In cases of the second group, which I shall soon proceed to consider, you will, however, see that it is a usual occurrence.

In the three cases I have just related you will have noticed that the injury—a severe blow or squeeze—did not initially

cause any breach of the external surface. Open wounds in the abdominal wall do not usually provoke much spreading inflammation unless complicated by the lodgment of contaminating substances; and, as you would naturally expect, clean incised wounds, even though extensive, are, of all, the least liable to such ill consequences; but severely bruised and badly lacerated wounds of the abdominal wall also often do remarkably well even though the surroundings of the wounded are insanitary and the care and attention that can be given to them are very imperfect, as must often be unavoidable in warfare, particularly when this is carried on in half civilised or barbarous countries. Thus I well remember the circumstances of two wounded men both lying at the same time in one of the huts of the General Hospital in the front before Sebastopol. One, an engineer, had the soft parts over the iliac crest torn and the crest itself bruised by a grazing cannon ball. The sloughing which followed this injury was very restricted, later a fragment of the crest exfoliated, the wound closed, he made a good recovery, and he is still alive. The other, a private in an infantry regiment, was hit on the right haunch by a fragment of an exploding shell which tore out a patch larger than the palm of the hand from his flank, comprising the muscles of the abdominal wall, and leaving behind only the peritoneum with a thin film of subserous fatty tissue, through which the intestines were apparent as if viewed through a piece of wetted tissue paper. I was greatly impressed by this evidence of the tenacity and elasticity possessed by the peritoneum. Strikingly little inflammation ensued in the borders of this ghastly wound. The torn muscular edges cleaned, granulations sprang up upon them, and also covered the peritoneum. The large area of the wound contracted, and after several weeks the wound was so small and the man's general condition so good that he was removed from the front to a base hospital; but where such a wound is complicated by the presence of infective substances, which cannot be completely removed or neutralised, the consequences—as you all, at our present standpoint, now understand—may be widely different. Let me, by way of contrast to the two preceding cases, mention to you a third. Nearly at the same time I received into one of my huts a bombardier whose right haunch had literally been shattered by a shell which burst close to him. The fleshy parts of the buttock, torn from the flank and perineum, hung as a great rug from the back of the upper part of the thigh. The innominate bone was comminuted. Below, the lower end of the rectum, with the prostate and base of the urinary bladder, was extruded, but neither viscus was opened. The immense wound, blackened by powder smoke, was also very soiled with dirt and many little pieces of straw from the bottom of the ambulance waggon on which he had been hurriedly laid with others wounded and brought to the hospital huts. Through the great pressure of circumstances at that moment—for the number of wounded was considerable—no precaution had been possible to guard the wound against soiling. An endeavour was made to remove all extraneous matters, but it was unavoidably imperfect. Diffuse phlegmonous inflammation rapidly supervened; it quickly overspread the trunk and lower limb, and on the third day he succumbed. He was a remarkably fine, muscular man. The immediate shock from this terrible injury was less than might have been expected; he rallied well, and the immediate cause of death appeared to me to be acute septic intoxication. But I find I have been travelling far away, and I will return to the practice of our own hospital, which should be for you a very familiar field. You will, I assume it as granted, readily comprehend that foreign substances are often lodged in a punctured wound and elude immediate detection, especially when the wound is inflicted by a relatively obtuse implement. There was a good example of this some time since in Forbes Ward, at that time occupied by surgical cases. The patient, a youth aged eighteen years employed on a farm, slipped off a stack and became impaled on a stake which, entering at the pubes, passed upwards between the skin and the recti muscles to above the level of the umbilicus. The stake was withdrawn and he was brought in a cart to the hospital. This injury was followed by extensive phlegmonous inflammation of the abdominal wall, necessitating free incisions, through which were extracted pieces of his clothing and of bark.

A large proportion, perhaps the majority, of instances of phlegmon and of abscess originating in the abdominal wall are, then, attributable to mechanical violence.

Of others in the first group proceeding from other causes—e.g., the liquefaction of a gumma—I shall not now speak. As I have already told you, this group is small, whereas the second group is comparatively large, its cases being relatively numerous. In the time that remains I will notice some cases of this latter group. Note, first, that the focus whence the abdominal wall is invaded may be near or distant; it may even be very remote, so distant as for a long time to elude detection. As aptly illustrating invasion of the abdominal wall from a near-lying inflammatory focus I cite the common course of perityphlitic suppuration, of which our wards are seldom long without examples. In most of these the nature of the disorder has been rightly recognised, and this so early that the inflammatory process in the abdominal wall has not passed beyond the phase of oedematous infiltration, when it is cut short by a timely incision into the abscess cavity in relation with the cæcum, its appendix, or the ascending colon. But this practice, now adopted by all surgeons, is of comparatively recent date, and I have thought that an able paper by the late Professor Sands of New York, in which he advocated early incision in cases of this kind, marks the turning point in the history of the treatment of perityphlitis, when expectancy, formerly the rule, began to be replaced by early surgical intervention. His early sudden death from heart disease, in the full possession of mental vigour, at the most active period of his surgical career, was a loss felt not only by his countrymen, but also by many on this side of the Atlantic, who knew and valued his writing, and by none deeper than by those who also knew the man.

Even now the existence of perityphlitis is occasionally overlooked and the significance of its symptoms misread. Not so very long since you might have seen in Bird Ward an example of what such oversight may lead to. On April 2nd, 1890, a very obese woman, of mixed European and Oriental parentage, was admitted into that ward. She had fever, a dry brown tongue, and was extremely feeble; in short, she had the aspect of one very gravely ill. The lower part of the right side of her abdomen was occupied by a large phlegmon, which extended inwards across the corresponding semilunar line, passed outwards over the Crista Ilii to the buttock, which was enormously swollen; and below the groin involved the upper thigh, or rather more, of the thigh. The buttock, centrally, was so elastic as to give the impression of there being deeply placed fluid, and over this area the skin had a dull red colour, its cuticle was blebbed, and in the subcutaneous tissues gaseous crackling was very distinct to the touch. The patient, a highly intelligent person, said that being then, as was supposed, in good health and without previous ailment, her present illness had begun on the 8th of the preceding month with frequent severe rigors and slighter shiverings. Having in earlier life been exposed to malaria, and having some knowledge of the fever such a miasm occasions, the significance of her symptoms was not at first appreciated. Later she was thought to have rheumatic fever, and she was placed in a hospital, where she remained under treatment by drugs until, finding herself becoming steadily worse, her friends removed her to her home and brought her thence to us. At this time she plainly had a very extensive and advanced gangrenous cellulitis or phlegmon of the abdominal wall, buttock, and thigh, with also septic intoxication. The scanty information elicited was insufficient to elucidate the origin of this. However, the treatment instantly required was not doubtful. Free and deep incisions were made into the phlegmon, giving escape to bubbles of fetid gas, to thin, discoloured, very offensive pus, and to large shreds of necrosed connective tissue. An attempt was made to check putrefaction by the free application of a solution of zinc chloride (forty grains to one ounce of water) and a large absorbent antiseptic dressing was put on. Next day other incisions were made and more sloughs were drawn out. Asepsis could not be attained. Fever continued and her prostration increased, notwithstanding the free administration of alcohol. On the following day pneumonia was evidently present, and on the fourth day after she entered our hospital death occurred. At the necropsy Dr. Voelcker found that the focus whence this huge phlegmon had started was an abscess with sloughy walls in the right iliac fossa. From this suppuration had spread upwards behind the ascending colon to the level of the middle of the kidney. Into this abscess cavity projected the vermiform appendix, which had in it one actual perforation and two small gangrenous spots. The front of the cæcum and ascending colon were agglutinated to the

parietal peritoneum along and above the pelvic brim, and the great omentum where lying upon the middle part of the ascending colon was also fixed by adhesions to the abdominal wall. The perityphlitic abscess had crossed the outer edge of the Musculus quadratus lumborum, and it had perforated the abdominal wall just above the Crista Ilii, so invading the buttock, where it had originated the gangrenous cellulitis which had so rapidly overrun this region, the abdominal wall, and the thigh. Can we doubt with our present experience of the good results obtained by early operative intervention in instances of perityphlitis that timely surgical interposition might here have saved a life?

I would ask you to bear in mind that, whilst many abscesses invading the abdominal wall from a focus in the right iliac fossa are primarily perityphlitic, all have not this origin. I will now cite such an instance. Some of you, I know, watched with interest this remarkable case. The patient was in Founder Ward, and was a man aged fifty years; he was admitted into the hospital on Feb. 9th, 1893. He had in the right side of the front of the abdomen, above the outer end of Poupart's ligament, distant two inches and a half from the Spina antica ilii, the external orifice of a sinus which led into the iliac fossa. Below this, in the upper part of the anterior and outer aspect of the thigh, was an oblong, prominent, conspicuous swelling, pressure on which caused the extrusion of pus from the orifice of the abdominal sinus. At the inner end of the groin was the scar of a recently healed incision. Deep in the iliac fossa an abnormal resistant fulness was felt. His complexion was sallow, his gums showed the blue margin characteristic of lead, and his bowels were habitually constive. He considered that he had had fair health until about twelve months previously, when he was laid up by a severe illness attended with great pain in the abdomen. This at first was regarded as a lead colic, but it did not yield to remedies. Later his abdomen was very swollen. Then an abscess pointed at the inner end of the groin and was opened by his surgeon; it closed and left the scar we saw there. Subsequently an abscess pointed and broke in the position of the sinus, persisting above the outer part of Poupart's ligament. His surgeon wrote that he had at one time regarded the case as one of perityphlitic abscess. After allowing him a few days' rest to recover from the exhaustion produced by his journey from the country he was placed under an anæsthetic and the swelling in the thigh, the sinus over Poupart's ligament, and the iliac fossa were explored. They were found filled with a soft myxomatous tissue centrally necrosing and suppurating. This neoplasm had invaded and infiltrated the Iliacus muscle and also the ventral surface of the Ilium, which was roughened by tufts of small crowded osteophytes. Anteriorly, the myxoma infiltrated the posterior wall of the cæcum and ascending colon, forming together with these a mass, in endeavouring to remove which the danger of opening the lumen of the gut was very present to me. It became obvious that although large masses of the neoplasm were removed with the scoop complete eradication was not attainable. The patient bore the operation well. On the third day, when the dressings were being changed, the discharge was found unmistakably fouled by fæces and fetid gases escaped. There could not be any doubt that the wall of the gut had given way. His condition, with occasional slight and very transitory improvement, progressively deteriorated. The iliac fossa again became filled with a large mass of tumour, which also extended upwards into the flank. Then, realising that his end was approaching, he had himself removed to his home, and after reaching it he died within a couple of days. His friends could not be persuaded to allow a necropsy. Here, then, an abscess which invaded the right inguinal region of the abdominal wall had its origin in central necrosis and suppuration of a deeply seated myxomatous tumour. Such a case is very exceptional; but analogous circumstances are not so very rare in connexion with certain intra-abdominal cancers. The following is an example.

A stout, grey-haired woman aged fifty years, but in appearance much older, addicted to taking as large quantities of ale and whisky as she could get, with a sallow complexion, flaccid cheeks, and face expressive of much suffering, was admitted into Bird Ward on July 21st, 1892. Centrally situated below her umbilicus was a conspicuously prominent red, glossy, acutely tender swelling, peripherally ill defined, of oval outline, measuring about four and a half and six inches in its long and short diameters. Peripherally brawny, centrally it was soft and fluctuated. She had a foul, dry

tongue, no appetite, and a high temperature. She told us that her health, which she had previously regarded as good, had been falling for nearly one year, during which time she had lost weight and had often had pains in the abdomen which she "laid to wind." These pains, she said, "came and went," and, she added, "they were sometimes worse than those of labour." As the swelling in the abdominal wall was obviously a phlegmon it was freely incised. Several ounces of very offensive pus and also masses of necrosed connective tissue were removed. The boundaries of the space whence these issued were scraped with a sharp scoop, after which the cavity was flushed with a solution of mercuric chloride, and an absorbent antiseptic dressing was applied. Next day her condition seemed slightly improved; but this amelioration was not sustained; a profuse puriform fetid discharge continued. Asepsis could not be obtained. She lost flesh and her strength continued to fail. In September a considerable intra-abdominal mass under the site of the sinus left after the phlegmon was detected. Obstinate diarrhoea set in and on Sept. 9th, 1892, she died, fifty days after she entered my ward and somewhat more than one year after the date of the first symptoms referable to the intra-abdominal disorder. Dr. Voelcker, by whom the necropsy was made, found below and to the left of the umbilicus a sinus passing through the abdominal wall into an intra-abdominal mass firmly adherent to it. This mass, of the size of a foetal head at term, comprised part of the Omentum majus, of the ascending, transverse, and descending colon, and small intestine infiltrated and agglutinated together by a neoplasm which to the unaided eye had appearances characteristic of cancer. This view of its nature was confirmed by microscopic examination. Here a cancer, perhaps originating in the omentum, had spread to the surrounding parts and increased until it formed with them a large tumour. Centrally necrosing and liquefying a foul abscess formed in it, which invaded and traversed the abdominal wall, inducing in this the phlegmon which brought her into the hospital. I may add that in the central hollow in the tumour a considerable cauliflower-like mass projected from its wall, and that the coats of the duodenum also were much thickened by cancerous infiltration, which had extensively broken down and of which little fungating bunches projected into the lumen of the gut.

Gentlemen, the clock tells me that the hour is spent, and I find that I have done little more than touch the fringe of the subject. Did time allow I would set out before you cases illustrating the invasion of the abdominal wall by abscesses which had their starting-point in an ulcer seated in one or other of the several segments of the digestive canal, or which began in the kidneys, in the liver, and even in the pancreas, or had their origin in the pelvis—of which women supply so many examples, but which are not restricted to their sex; and, these having been dealt with, the subject would still be unexhausted. I hope to return to it at some future time as occasion arises.

In Address

ON

EXPERIMENTAL CRANIOTOMY AND DIAGNOSIS OF CEREBRAL ABSCESS.

By PROFESSOR AUGUSTO MURRI, M.D.,

PROFESSOR OF MEDICINE IN THE UNIVERSITY OF BOLOGNA.

Delivered on Nov. 30th, 1894, before the Lombard Medical Association, and specially reported and translated for THE LANCET.

GENTLEMEN,—When your eminent President conferred on me the honour of an invitation to discuss before you some subject deserving of your attention my wish to comply led me to an assent so ready that it afterwards struck me as almost precipitous. The choice of a subject proved difficult. If I now inform you that I am about to treat of some of the reasons which justify, or at least necessitate the study of, craniotomy it is because I think the subject will be interesting to all. One hardly knows whether the subject is more a medical or a surgical one, but it seems to me that no one who has made a study of the healing art can be indifferent to it. I therefore

hope that none of you will disapprove of it. At this critical moment, when it seems that we are about to gain the mastery over one of the most terrible maladies, the discussion of another disease, which, though serious, is rare, lacks the power to arouse any great enthusiasm or hopes. But the clinic has not the privilege of a laboratory which may follow out a research to its extreme limits; it must cease where facts fail, and therefore the progress is sure but slow. Nevertheless, those among my audience who work in the laboratories will not consider my subject extraneous to them, since the tree from which modern brain surgery has derived such beneficial fruit has many of its roots in the ideas suggested by experimentalists. Before continuing I must confess that I speak as a medical practitioner, not as one of those numerous clinicians who study from the actual cases things which could as well be learned from any chemist, histologist, or bacteriologist who had never entered a hospital. The patient offers facts well known to the anatomist, physiologist, chemist, pathologist, and so on, but also other facts which none but a medical practitioner can perceive, and these constitute the actual wealth of the clinic. This I know is the old-fashioned clinic, but it will be the clinic of ages, though its brilliance may not be dazzling. This modest and useful clinic is also a branch of science; and, indeed, do we not in a great measure owe to the symptoms which medical practitioners have noted in patients all that we know of the brain, which is precisely the organ of which I am about to speak? The clinical student, as the observer and interpreter of the phenomena of the mechanism of the brain, knows, however, that progress in this path is arduous and slow. Like all other scientists, he must resign himself to await the solution of a thousand problems. But the clinical student is not only a scientist, he is also a man called to the aid of his suffering fellow creatures, and if as such he must always work in a sphere free of all incertitude work would no longer be possible to him. Resignation would cease to be a virtue; he must act while still awaiting the solution of those scientific problems. That scientist is most to be commended whose conclusions are most circumspect and precise; he must wait for clearer lights before making assertions. The medical practitioner, on the other hand, is obliged to act either in total darkness or in the faint light of a distant dawn. Science is not only for posterity. A science, however advanced it may be, only constitutes an elementary knowledge, since it suggests more questions to be answered in the future than there are answers in the past. As Goethe used to say: "Every problem that is solved gives rise to hundreds more." Blessed are those scientific deductions which can be safely applied to daily practice, but woe to us if our only means of influencing the vicissitudes of humanity were through fixed scientific deductions. When scarcely emerged from speculation, and entered into one of the active paths of life, man soon becomes aware that the ground is trembling beneath him. A general who is arranging the plan of a campaign, a financier who introduces a new system of taxes, a legislator who promulgates a code, an agriculturist who starts a new method of cultivation—all obey the precepts imposed by their respective sciences; none of these find their practical problems so free of unknown quantities as to render their prevision of the result sure and unailing. Indeed, history is full of examples showing that the most reasonable previsions are often fallacious, because in every work of humanity there is always a want of knowledge of the factors of which the practical problem is composed.

It is no wonder that even a medical man has often to act with an incomplete knowledge of his problem. Some people have a characteristic aversion to anything that is not exact and sure. This gift, I repeat, is excellent in the pure scientist, but in practice it tends to restrict the coöperation of medical art to those cases in which the unknown quantities of the problem are eliminated. Thus, in the subject I have chosen, many hold that the cranium cannot be operated upon unless one is certain that the surgical instrument will find the lesion of the brain in the exact spot and exact conditions foreseen before operating. This numerous party has for its leader the well-known Bergmann. His work on the surgical cure of cerebral diseases¹ guides the hand and the mind of the greater part of surgeons. Clinical practitioners are for the most part of the same opinion. Sahli writes: "I am entirely of von Bergmann's opinion that cerebral surgery must first of all win favour by a choice of absolutely accurate

¹ Die Chirurgische Behandlung der Hirnkrankheiten. Berlin, 1889.

cases." Professor Martius² says: "Bergmann's³ book on the brain, written with a perfect mastery of the subject, constitutes unconditional authority." But, however eminent the author may be, and however admirable his work, I must confess my dissent from the fundamental thought which underlies it. If I am obliged to mention the name of this eminent surgeon too often let it be understood that it is on account of the preponderant importance that his word on the subject has over that of others who profess to hold the same opinions. Professor Bergmann clearly states that "it is evident that he wishes to put the interests of the surgeons in the first place." According to him, or rather to his opinion, it is better to restrict the limits of surgery rather than enlarge them. Nowadays, holding the opinion that an operation is *per se* entirely without danger, one is inclined, notwithstanding the uncertainty of the diagnosis, to use the lancet and the scalpel in order to see whether there is some morbid growth to be removed. In other words, we are inclined to be daring without reflecting what should be the reward and aim of audacity. Bergmann does not intend to detract from the powers of surgery, although in his present studies he is trying to find, above all, the conditions in which an operation has the greatest probability of success, and limits himself to such cases. In doing this he omits many cases which, under more favourable circumstances, might have been operated upon. But he "does not wish to leave to chance that which should be exclusively the result of a critically weighed experience and of a strictly scientific proof."⁴ This fundamental thought runs through the whole work. Thus, on p. 110 he repeats that "only a clinical diagnosis can ensure progress in the efficiency and power of the operating surgeon"; and on p. 176: "I cannot excuse the surgeon who, believing in the slightness of the danger of operations, is inclined to operate without much thought to see whether it will succeed in the case. I shall always be opposed to this aimless proceeding (*planloses Vorgehen*). On the other hand, I think it is not only allowable, but absolutely obligatory, to make use of what has been furnished us in experiments on animals at the bedside of a patient. . . . I expect true progress in cerebral surgery from a wise limitation." There are too many things in Bergmann's opinions that do not seem to me quite fair. The interests of surgery are doubtless to be respected, but morally they are as nothing compared to our duty towards a man who is dying; and when he grants that by following his advice we should be leaving without an operation many cases which might be beneficially treated by the surgeon I begin to doubt whether his advice can be ethically justified. Why should we renounce a possible good? The morbid processes of the brain, which surgery is called upon to heal, are almost all possibly fatal, and a dying man has not only the right to demand of us a certain cure, but also that which for lack of any certain means offers his only hope for relief. Which of us, knowing that some person dear to him is suffering from an abscess or an intracranial tumour of doubtful diagnosis, would watch him slowly, surely, cruelly dying without attempting the only expedient that might save him? It might be an exaggeration to assert that the act of operation in itself is innocuous, but in the face of the most serious suffering and the gravest prognosis I should place little value on the objection. If a man were drowning and begged you to give him a rope, would you dare to reply that *perhaps* the rope might not be strong enough? Unfortunately, none of our remedies are absolutely sure; none have an absolutely beneficial action free from noxious qualities. It is, I allow, a mere difference of degree, and opening of the skull in certain doubtful cases may give more reason for fear than hope of success. But I repeat that intracranial diseases are so serious that the precept of "do no harm" cannot be applied to them since the condition of the patient can scarcely be worse, while the benefits that might accrue are great. I can well understand that, as far as the *amour propre* of the operator is concerned, there would be little temptation to open the cranium if it were only to leave the patient in his former condition.

Modern surgeons have grown accustomed to so many triumphs. I admit, in so far as the interests of the operators are concerned, it would be preferable to follow Bergmann's advice—that is, to operate only in the few cases in which the result would undoubtedly be beneficial; but the interests of the patients oppose this. Science, as I have already remarked,

must serve for our contemporaries, and it is to the medical practitioner that the duty falls of making use of all scientific discoveries and deriving from them the greatest possible use and service. Modern science shows us how to cure chronic cerebral abscess. Now, to deny the advantage to some people of this discovery because it cannot always be strictly applied would be to place the method of proceeding before a love of humanity, and if such a thing were blameworthy in a scientist of a laboratory it would be unpardonable in a medical man who works by means of knowledge, but whose aim in working is and must be charity. It is certainly a fine thing for a master to aspire to give to all surgeons some unfailing rules of conduct, and it is also well for him to severely reprove that blind method of working which is so convenient for ignorant men and quacks. But it would be unfair to deprive the present generation of the benefits which modern knowledge has conferred only because the method of adopting them has not yet been made clear. Here, indeed, there is not a perfect uniformity between scientific and practical aims. That semi-knowledge which in a scientist only serves as a stimulus to research is already a power to the practitioner. Attentive observation, however, assures us that absolute knowledge never comes directly to the practitioner, but little by little, by means of continual corrections. It would no doubt be preferable if practical rules were turned out ready made from the laboratory, but this is impossible, because, as has been frequently said, the conditions of an animal that has been experimented upon are similar to, but not identical with, those of a sick man. Although experimental science has already taught us a great deal in the normal and abnormal action of the brain, it nevertheless is true that the natural history of an abscess, a tumour, or thrombus in the sinuses of the human brain must be told, and has partly been already told, by means of observations of the sick man. Thus, although experimental physiology has taught the surgeon many things, the lessons of most value to him are derived from his observations during operations on a diseased human brain. If by an aimless proceeding (*planloses Vorgehen*) we are to understand the opening of the cranial cavity wherever it may be, or for whatever reason, we should certainly all be of the opinion of the Berlin clinic. If the ignorance is merely individual, to operate for personal enlightenment would be wrong; but if the ignorance is the result of an inability to obtain actual knowledge it is an absolute duty to procure enlightenment even by means of operating, providing the operation be not harmful. There is no doubt that sometimes one operates on the abdomen without absolute need, and this is sometimes undeniably attended with ill results; but is it possible that anyone would open the cranium without expecting to find a morbid growth and without attempting to remove it? True, presumptions may have but a weak foundation; they may be aims not entirely justified, but true experience is gained through the mistakes made. The clinic can teach what the laboratory never will—that is, whether, how, when, and up to what point a brain with a tumour, an abscess, or a thrombus of the venous sinuses with a cicatrix causing epilepsy can be operated upon without danger or with a good result. If this is a *planloses Vorgehen*, then there exists no remedy, not even the best known, which does not partly originate in this very modest beginning. How much digitalis has been used during the last twenty or thirty years in physiological and chemical laboratories? It is certain that the knowledge we have acquired is valuable and precise, but the careful experience of the clinic, the errors of some imprudent practitioner, and chance poisonings become our safest guides when we wish to profit by the wonderfully beneficent action of this plant. So true is it that, even after continual experimental researches, we have not yet succeeded in explaining the reasons for the rules which experience has sanctioned. Not even the happiest clinical applications of experimental knowledge can be entirely exempt from a certain amount of conjecture and practical correction. Bergmann says: "If in experiments on animals the extirpation of a part of the skin has been found useful the same course must be applied to analogous cases otherwise incurable in human disease." I agree with him, but, nevertheless, there is no identity between the dogs of Munk, Heidenhain, and Novi, in which the extirpation of the entire motor zone on one side arrested convulsions, and the patients cured of epilepsy by the removal of a splinter of bone or of a cicatrix on the skin; man's brain is often so much changed by the continual influence of trauma that the immediate action of excitement is not

² Die Hirnchirurgischen Operationen, p. 10. Leipzig, 1891.

³ Beiträge zur Lehre vom Hirnabszess, p. 66. Berlin, 1891.

⁴ Op. cit., p. 3.

only to produce a fit of convulsions, but to slowly modify the brain as regards its nutrition and all its functions. I repeat that it really becomes a different brain from what it was even after the splinter or the cicatrix has been removed. It is, therefore, a different thing to arrest an epileptoid convulsion produced by the experimentalist in a dog and to cure epileptic neurosis produced by trauma in man. There may be some analogy between the two phenomena, but I do not think that "the cases of traumatic cortical epilepsy entirely correspond with the result of the experiments in animals." Bergmann⁵ asserts this, led away perhaps by the natural and universal desire of acting upon scientific deductions; but the truth is that the final and absolute decision as to the efficacy of a surgical cure for traumatic epilepsy appertains to the experience of the clinic, which will certainly not proceed without a pre-established method, but will meet, as it already has met, with many unknown quantities and surprises; thus a certain amount of *planloses Vorgehen* must be encountered even in subjects which, superficially examined, seem the most positive. And can one wonder at it? Human pathology is made up of a number of phenomena peculiar to itself, analogous to, but not identical with, others, and both physicians and surgeons must experiment on them; therefore, they must act as all other experimentalists do. To gain knowledge they must make proof after proof, but always on these same phenomena, not on different ones; therefore, a state of twilight must always precede the light of perfect knowledge, and consequently a period of uncertain action, which it would be unfair to call a *planloses Vorgehen*, is inevitable if we would attain to a possession of safe rules—a true and worthy ideal of practical life, an ideal to which one attains through a direct knowledge of facts, not through deductions more or less like the truth. Do not think from this that I am one who does not respect the knowledge that inspires, guides, and illustrates every clinical experiment, but I hold that they are not the only means of deciding as to the utility of a curative expedient. I have been obliged to prove this to draw the conclusion that we cannot yet assert complete knowledge of all cases in which a surgical operation may serve to cure a cerebral disease. Clinical experience, our best teacher on such subjects, has not yet been sufficiently consulted; it is therefore premature to restrict operation to a few cases in which it will undoubtedly succeed before knowing whether it may not prove beneficial in others. It is not only the humane desire to save a dying patient, but science also demands a more frequent use of surgery in intracranial diseases. If we neglect to profit by the occasions that offer, how shall we ever acquire a knowledge of facts, which aid to form a practical and safe rule? Yet such is the power of a name that the wealth of clinical experience increases but slowly. I assert that whenever a competent examination of the symptoms and course of a cerebral disease brings us to the necessity of a diagnosis of lethal intracranial process operation is justified even though the seat and nature of it render the result uncertain.

From certain of Bergmann's sentences one might say that he is hostile to this idea. Here are some, for example. "If the absence of inflammatory symptoms prevents a precise indication of the seat of a tumour we cannot even speak of an explorative trepanning."⁶ "I do not think trepanning or incision of the brain is justified unless peremptorily demanded by unmistakable and overt symptoms."⁷ "I advise operation in cerebral abscess only in so-called typical cases" (p. 88). "We do not treat of finding out at all costs every cerebral or cerebellar abscess; but it is of importance not to leave unoperated on those which clinical experience permits us to diagnose" (p. 90). In Jacksonian epilepsy "we should never operate except when there is a full reason to admit a palpable cortical lesion, and hence removable" (p. 162). I have intentionally accentuated these words of Bergmann, *precise indication, unmistakable, typical cases, full reason*, because they show that the illustrious clinician starts with the idea that it is possible to arrive at a precise and certain diagnosis. It may seem strange to some, but I hold it true that we may frequently formulate a diagnosis sufficiently precise in an intracranial lesion; but in most cases the judgment is a mere probability. This *certainty* of diagnosis, which would be invaluable to the surgeon, generally does not exist. Well-argued diagnoses, thought out with great precision, are made, and especially are published; but the merit must too often be given to good fortune in the cases, for all equally

sure diagnoses sometimes prove mistaken. The origin of the symptoms in intracranial diseases is so complex that some element caused by them remains unknown to the physician, and therefore the clinical inference can never be utterly certain. Not that the correspondence of the anatomical lesion with the clinical inference is a mere accident; indeed, I affirm that in no other branch is the practical value of the physician more clearly proved. I only maintain that the certainty which seems to be an essential condition, and without which Bergmann will not consent to employ the surgeon, is but rarely attainable. When an anatomist or surgeon opens the cranium he always finds something unforeseen. Even when right as to the fundamental fact, some condition which should have been certain is wanting, and another neither suspected nor thought of is conspicuous. Bergmann has not deceived himself on this point. He says, in one part of his famous work: "I believe it right to assign a limited field to operation, reserving it only to the few cases precisely diagnosed." Yet even for these it has, in the first instance, no other importance than that of an exploration—i.e., an operation made to obtain a more direct investigation. It is only after the aperture is made that the surgeon can judge whether the tumour is within reach, and whether, when found, its size, its relation to the neighbouring parts, and its infiltration into them do not forbid removal. The surgeon should be always ready to interrupt or to abandon the operation either sooner or later. And this happened to the illustrious surgeon himself in a case in which he had occasion to admire the excellent diagnostic directions of his colleague Jastrowitz. Where, then, is the certainty? I know that the interests of surgeons demand that these cases should be eliminated from the limited number admitted by Bergmann; but how are we to recognise them? Those who pass the clinic—and they are many—by means of books on physiology and pathology may pretend to succeed; but those who study real disease and make post-mortem examinations will confess that it is still mostly impossible to distinguish certain circumstances of volume, infiltration, and vicinity. Bergmann entirely appreciates this difficulty. If our object is the good of humanity we must invert thus the sentence of the Berlin clinic: We must not treat only those few cases which are clinically pronounced to be adapted for operation, but must operate in all cases which might possibly be treated by the surgeon. Surgery loses nothing by attempting in some cases without succeeding; it would, I believe, lose more if through fear of attempting in vain we let men die when they might have had the inestimable privilege of life. The choice lies between these two systems—either operate in only a few cases or else resign ourselves to dare non-successes in some in the hope of success in the many. In the first course the surgeon is less likely to find that his work is ineffectual; but he must confess he may have renounced some signal triumphs and has missed that knowledge which repays practical experience. Following the second system he avoids these two evils. True, some mortification to the surgeon may ensue; but what does this matter in the face of a clear conscience and increased experience? You might say that ignorant people, seeing a surgeon's attempts frequently fail, might lose faith in him; but to an invalid blind faith is no longer a guide. The patient only wants to get well, and I wager that if the alternative were clearly placed before him he would refuse no reasonable chance of recovery where it is certain that without this pain, blindness, paralysis, or death must inevitably ensue. Unfortunately I am not qualified to speak to surgeons as a surgeon; but if it may be allowed to an outsider to give his advice I should say it is the interest of the surgeon to increase as far as possible the number of his cures. And if they object that this method is not scientific, I reply that one may respect knowledge when useful or even dangerous, but a science that allows people to die when they might live is neither powerful nor humane.

I have perhaps insisted too much on this moral side of the question, and this may weaken my thesis, for it may be deemed that sentiment rather than reason has inspired it. I will, then, at once begin to demonstrate more fully the assertions I have indicated, which form the basis of my theme. In the first place, we must admit that criteria for determining during life the seat and nature of an intracranial lesion are less reliable than is generally believed. The marvellous experience of Frietsch and Hitzig, the observations of Jackson, Charcot, and others, have in truth revealed an unexplored world, but

⁵ Op. cit., p. 177. ⁶ Op. cit., p. 112. ⁷ Op. cit., p. 83.

the diagnostic importance of these discoveries has been greatly exaggerated. The uncertain and unknown quantities which are enveloped in the cranial covering (not to mention the psychic qualities) are such that, even when the skull is opened and the brain cut into, one or more problems remain unsolved. Proofs abound of the truth of this; yet the nature no less than the seat of these lesions remains difficult to recognise. It lies, therefore, with the unprejudiced clinical professor to moderate too enthusiastic a faith, and to give an example of modesty and fallibility. As I have to enter into a minute analysis of facts I must restrict myself to one single disease—chronic cerebral abscess. Glancing at the history of the intracranial abscess we recognise this singular fact: the treatment of this disease has made great advance of late years, while the diagnosis is still very insufficient. The medical man can treat a chronic cerebral abscess, but he does not know how to recognise it. This is the exact opposite of what happens in other maladies. Macewen⁸ has had 31 cases of intracranial abscess, and has operated on 25; the 6 not operated upon all died; of the 25 operated on, only 2 succumbed, one because during the operation an abscess on the cerebellum remained occult, and the other because the operation was not performed till the patient was already on the point of death.⁹ On the other hand Martius has made a deep study of seventeen cases of cerebral abscess, occurring in the German hospitals during the few past years.¹⁰ Well, not one of these cases was revealed during life, and naturally of the seventeen cases none were operated on, and none recovered. Now, we all know that the training of German medical men is second to none, and we cannot deny that this utter absence of diagnosis is very significant. Probably, if we all wish to be as sincere as the registrars of the German military hospitals we should feel the difficulty or impossibility of recognising a chronic cerebral abscess during life is widely spread, and we should not find in certain text-books precepts which have no similarity to facts. It is true that acute cerebral abscess and traumatic purulent meningitis are generally easily diagnosed, but besides these acute cases there are many chronic or subacute ones, in which the judgment of the medical attendant is often at fault. If you reflect, the greatest argument in chronic cases is in the etiological criterion—trauma, purulent otitis, diseases of the heart or respiratory organs, caries of the skull bones, &c. But the etiological criterion, valuable where it confirms a judgment, is weak where it has to form a basis, because, as has a thousand times been demonstrated, that which we call cause is really but a part of the cause; hence we can never make an *a priori* assertion unless there coöperate with that part all the other elements without which that one would be unable to generate the supposed effect. And this is why not all cases of otitis or affections of the lungs or caries of skull bones are followed by suppuration of the cerebral meninges or by an abscess in the brain; and whereas in all these numerous cases the patient who escapes intracranial suppuration might, like anyone else, be attacked from other causes by tuberculous meningitis, cerebral tumour, or some other brain process, the conclusion drawn from knowing the cause, though it may often touch the truth, is not *de rigueur*, and is thus subject to error.

There is, I admit, the semeiological criterion, but even this is indistinct and often of slight value. Bergmann divides into three groups the symptoms of cerebral abscess: (1) symptoms of suppuration, (2) symptoms of cerebral compression, and (3) local symptoms. But if we analyse these we find little or nothing remains to prove the abscess. Inflammatory symptoms often denote that a part of the brain is excited or paralysed—and nothing more. They tell us nothing of how the nervous tissue is injured. As a general rule these symptoms are either wanting in the chronic abscess or appear at a later date; but, since they might exist, this generic knowledge of their frequency aids us little or nothing in the treatment of the patient, because it always remains to be proved why a patient with inflammatory symptoms should not be suffering from one of those abscesses which are generally accompanied by inflammation, or why a patient without such symptoms should not have rather one of those rare neoplasms, which run a semilient course, or with only ordinary pheno-

mena. General ideas belong to the pathologist and serve also for the clinical student, but the latter must, above all, probe to the foundation of individual phenomena and not apply to them mere general principles. Neither do the phenomena of cerebral compression belong exclusively to the abscess, but also to neoplasms, parasites, aneurysms, meningitis, and even hæmorrhage. Bergmann brings into special relief headaches and congestion of the papillæ; the one because it increases with the access of fever, and the other because it is found in very few cases. However, neither of these things will hold; any headache, however caused, will increase with fever, and a blow on the head, whether in a case of abscess or tumour, may or may not increase the pain; optic neuritis is less uncommon than has been supposed as a concomitant of abscess.

In conclusion, when the physician is enabled to establish that a given part of the brain is altered, and by a process which augments the intracranial pressure, he has no doubt pointed out two attributes of the abscess; but as these same attributes belong equally to other morbid processes he cannot logically draw a final deduction unless aided by some attributes exclusively belonging to the abscess and to no other disease. The symptoms of the third group, those of suppuration, might assist here, but unfortunately these are almost all reduced to fever. Now the beginning of a chronic abscess of the brain is often so obscure and indistinct that the fever might be unnoticed; the development of suppuration in a tissue which, like the brain, is so little disposed to suppurate is so slight and slow that the pyrogenous substances developed by it either do not raise the temperature or raise it very slightly. Besides, the capsule with which the pus in chronic abscesses is surrounded, its biological properties, and the modifications which time perpetrates in the matter enclosed within it all combine to give it an individual existence, and thus to diminish the influence exercised by it upon its surroundings.¹¹ So it is, at least, until some accident or new development supervenes to modify the reciprocal attitude of the abscess and the surrounding tissues. This accident will then determine those ulterior cerebral alterations which constitute the cause of the terminal symptoms of chronic abscess in the brain. If, however, we reflect that meningitis may also cause fever and that many intracranial lesions occasion meningitis the value of these symptoms is lessened even in favourable cases in which they are found. Not to be diffuse, I will be silent as to the inflammatory action which might arise on the affection of certain parts of the brain independently of the nature of the process which causes it.

(To be continued.)

An Address

ON

EVIDENCE AND THE VALUE OF FACTS.

Delivered to the Medical Society, University College, London, on the Annual Public Night, Oct. 17th, 1894.

By J. BLAND SUTTON, F.R.C.S.,

ASSISTANT SURGEON, MIDDLESEX HOSPITAL.

GENTLEMEN,—Some years ago I heard a distinguished judge in an after-dinner speech remark that if the theories current in the profession of medicine were tried as causes before a judge and jury, and the testimony admitted on the principles prevailing in courts-of-law, the major proportion of them would fail. Few of us who have given serious attention

¹¹ Körner (Die Oertlichen Erkrankungen des Hirns; Frankfurt-am-Main, 1894, p. 93) opposes this idea. He says: "Abgekapselte Hirnabscesse wachsen vielmehr ebenso wie freie, bis sie in einen Ventrikel durchbrechen oder auf andere Art den Tod herbeiführen." This assertion is at best an over-statement of a truth. That encapsulated abscesses increase is true, but they do not, like others, increase to the end of their course. It is inexplicable why for so long they produce no functional disturbance, and why even after many months they preserve their small volume. We cannot certainly establish any absolute relation between the age of the abscess and the denseness of the pseudomembrane, but neither can we deny that the longer an abscess lasts the more frequently it is encapsuled; but it is absolutely incontestable that during the period in which it is entirely enclosed by a pseudomembrane the effect it causes on the cerebrum is less than when it is not so enclosed by a capsule.

⁸ Pyogenic Infective Diseases of the Brain. Glasgow, 1893.

⁹ We are treating of abscesses not wholly chronic or acute, but this need not alter much the result of surgical treatment; at least we have no facts to prove a difference in the efficacy of surgical cure for chronic abscess.

¹⁰ Beiträge zur Lehre vom Hirnabscess. Berlin, 1891.

to the subject can doubt the truth of that statement. It is deplorable how largely imperfect observation, loose and incomplete records, reverence for authority, professional bias, and incompetent witnesses promote error and retard truth. In this address the word "evidence" will be employed in its simple sense, signifying facts apprehended by the mind and made the ground of knowledge and belief. The term "fact" will be used to express what is certain and known by the evidence of the senses (Stephens). It is clear that facts are acquired by observation, hence it is manifest that we must carefully distinguish between what we observe and what we think we observe—not always an easy matter. It is a curious circumstance that the greater proportion of men and women prefer to believe what they think they see, especially in things apparently extraordinary, rather than exert themselves to establish the truth. For example, it seems somewhat strange that a crowd of educated persons could mistake an ostrich for a giraffe. Some years ago the passengers of an Indian steamship were greatly excited by observing on the shore of the Red Sea what they believed to be a number of giraffes. Of the reality of the observation they were convinced. It happened that a very able naturalist and surgeon on board, surprised that giraffes should have wandered so far from their usual district, watched the animals carefully and perseveringly, and at last proved clearly that the supposed giraffes were ostriches magnified by the peculiar atmospheric conditions prevalent over sandy tracts in tropical regions.

As facts are the basis of evidence it is very necessary to establish them beyond dispute. This is not always a simple matter. Remember that repeated reiteration will not turn statements into facts. Le Sage, in his admirable "Gil Blas," a book abounding in parables, tells of one Señor Carlos Alonso de la Ventolera, who "has got a number of good stories by heart, which he has repeated and vouched for so often that at length he actually believes them to be true." I fear we all know such a señor. Many illogical deductions arise from ill-observed facts in common life as well as in what is pompously called science, and have formed the basis of many satirical fables. On the other hand, facts which happen uniformly under the same circumstances not only become useful for the foundation of laws, but enable us to check careless observation and avoid erroneous judgment. It will be useful to illustrate this. Dr. Hedley sent me from Middlesbrough an acardiac foetus. It was headless, with rudimentary arms and ill-formed legs. The mother explained matters in this way: when some months advanced in pregnancy she visited a menagerie and saw a girl put her head into a lion's mouth. The "king of beasts" acted in an undignified manner and bit the foolish performer; this caused great consternation among the audience, and profoundly agitated this pregnant woman. To this event she attributed the disaster to her infant. In acknowledging Dr. Hedley's present I expressed the opinion that the foetus was one of twins and the companion was a girl. This proved to be correct. The mother's belief that the deformation of her child was due to the fright at the menagerie was based on an illogical consideration of the circumstances. Many, very many, headless foetuses (acardiacs) are born, and the mothers who conceived them have never been witnesses of a decapitation during their pregnancies. In the present case the facts are not in accord: the lion bit the girl, but did not bite her head off, yet the foetus was headless, arms rudimentary, legs ill formed, &c. The common-sense (scientific, if you will) side of the case is much more interesting, as it illustrates that facts which happen uniformly under similar circumstances serve as foundations for laws. Prolonged and careful study of the environment of acardiacs has shown that they always occur in twin births with a conjoint placenta, and when it is possible to determine the sex of the acardiac it is always the same as that of its companion. I have assured myself of this so often that on examining the specimen I was quite certain it was one of twins, its companion a girl, and the mother's story a compound of ignorance and superstition. When, after a number of careful observations, certain facts have been found to happen uniformly under similar circumstances, a discordant fact breaks the series, it is necessary to submit it to very critical examination, especially when the previous uniform events have been made the basis of a theory, because "one single fact clearly irreconcilable with a theory involves its rejection" (Jevons). For instance, a friend, possessed of a very large amount of inquisitiveness, once showed me a calculus as large as a

cricket ball which he had found in the colon of a horse. In explaining its nature I mentioned that he would probably find in the centre of the calculus a piece of metal or perhaps a button. Next day he amused himself by dividing the calculus equatorially, but was disappointed at the absence of any trace of a foreign body and had a good laugh at my expense. When his merriment was at full height one of the hemispheres fell to the ground and split in two, displaying a button. In this case my opinion was based on facts obtained from the critical examination of scores of colic calculi obtained from horses. Most of them had a fragment of metal as a nucleus; in a few the nucleus, as in this example, was a button. When an individual possessed of an average intellect makes a series of careful observations with a particular object in view he is said to have acquired experience, and one of the chief outcomes of such experience is a capability over the inexperienced in estimating probabilities. In the case of the colic calculus just considered experience enabled me to be quite sure that a foreign body would be found within it, and enabled me to state with a fair amount of probability that it might be a button.

Many can scarcely be aware of the great difficulty which is sometimes experienced in establishing a fact, especially when it may form the basis of a far-reaching principle. It happens occasionally that facts in favour of a particular theory appear extremely probable, yet fail to convince cautious minds; then by a favourable concatenation of circumstances a fact is observed which absolutely decides the question. To such the term "crucial fact" may be applied without giving it the great importance of Bacon's "experimentum crucis" or Herschell's "crucial instance." Crucial facts are often of great value, and as they are somewhat uncommon it is necessary to be patient and industrious in order to detect them. Their utility is demonstrated in the following example. It has long been known that an ovum may be fertilised and retained in the Fallopian tube. In 1889 I was able to prove that an ovum developing in the tube may, like an ovum in the uterus, be converted into what is technically known as a mole. Careful studies of typical tubal moles show that they are usually ovoid; on section they present an outer limiting membrane—the chorion, beset with villi; the greater part of the mole consists of blood-clot, but towards one pole will be found a cavity lined with delicate membrane—the amnion, which sometimes contains an embryo. (Fig. 1.) In many small

FIG. 1.

Tubal mole in section (natural size). F, Fetus. A, Amnion. B, Clot. C, Chorion.

tubal moles the amniotic cavity is obliterated. During a period of four years the excentric position of the amniotic cavity in tubal moles puzzled me. At last I obtained and described to the Obstetrical Society of London a tubal ovum with its membranes intact. In the early ovum the disposition of the membranes is different from what pertains at a later period. Soon after the chorion is shaggy with villi the embryo will be found in its amnion. Between the amnion and chorion there exists a space (well known to embryologists), which may be called the "subchorionic space," filled with fluid. (Fig. 2.) As the embryo grows the amnion gradually encroaches on and finally obliterates this space, but for a period a potential space exists between the two membranes, resembling that between the visceral and parietal pleurae. (Fig. 3.)

On examining tubal moles in the light of these facts it is clear that the blood occupies the subchorionic space. This at once offers a satisfactory explanation of the elliptical shape of tubal moles and also convinced me that in these circumstances the blood, in order to occupy this space, should come from within the ovum—probably from the allantoic vessels. When these views were communicated to the Obstetrical Society Dr. Horrocks suggested that, in order to make the evidence complete, it might be possible to demonstrate differences in the microscopical characters of the blood within the mole as compared with adult blood. The next fresh tubal mole which came under my notice was

FIG. 2.

submitted to this critical test. The red corpuscles exhibited the nucleated character which distinguish the blood of the early embryo from the adult. This simple fact makes it clear that tubal moles are due to blood extravasated from the ovular vessels into the subchorionic space. As the most convincing piece of evidence is the presence of nucleated red corpuscles it may be called a crucial fact.

Thus far we have mainly been dealing with facts. It will be useful now to consider the way in which they are employed as a foundation for judgment. For this purpose it is necessary not merely to apprehend but to appreciate facts,

FIG. 3.

a complex mental process known as reasoning. The appreciation of facts depends in a large measure upon the knowledge of the observer, for as a rule we only appreciate—and, indeed, often only perceive—those things which previous experience teaches us to expect. Individuals capable of perceiving facts previously unrecognised are termed “original observers.” Many are able to detect new facts, yet fail to reason upon them correctly, but when acute powers of observation and great capacity for reasoning are combined in the same person the result is a genius. Many men have distinguished themselves as patient collectors of facts, of these John Hunter and Richard Owen are remarkable examples; but to this exceptional talent for accumulating observations

add an unusual capacity for reasoning upon them—the result is a Newton, a Cuvier, or a Darwin. A combination of the faculty for accurate observation and ability to reason correctly on observed facts is essential in the successful practice of medicine and surgery, where much of the evidence on which judgments (technically called “diagnoses”) are formed is of the kind familiar to lawyers as “circumstantial evidence.” The best legal writers find it impossible to define circumstantial evidence, and I shall adopt their method and illustrate it by examples.

In 1874, when the remains of the intrepid David Livingstone, “brought by faithful hands over land and sea,” reached England, grave doubts were expressed as to the authenticity of the mummified corpse; recognition by means of the face was impossible. It was well known that Livingstone during his last visit to London consulted Fergusson in regard to an ununited fracture of the left humerus, the result of a bite from a lion in 1843. Fergusson, in company with other surgeons, examined the left humerus and found an ununited fracture a little below the insertion of the deltoid. A critical examination of the parts revealed the peculiar changes characteristic of an old ununited fracture: “the ends of the fragments were surrounded by a capsule, an inch shortening compared with its fellow, and marked attenuation of the humerus, especially in its upper half.” These facts coincided with Fergusson’s previous knowledge of the case, and reasoning on the facts he writes “that a specimen of this unusual condition should arrive in London from Central Africa except in Livingstone is beyond human credulity.” A cast of the bone is preserved in the museum of the Royal College of Surgeons of England.

Let me now draw your attention to a tale of painful interest illustrating evidence of the same kind. In 1892 H.M. gunboat *Partridge* was sent by the Commodore to ascertain the truth or otherwise of a statement that some men were marooned on Roncador, a small coral island (300 by 200 feet), or cay, in the Caribbean Sea. On arriving at Roncador it was found occupied by sea birds, especially boobies, in enormous number; some huts were also observed. On landing and entering the largest hut the scene depicted in Fig. 4 met the gaze of the explorers. Half sitting, half reclining on a high trestle bed, and partially supported by a makeshift crutch, was something rigid and angular within a mouldy cotton shirt and canvas trousers. Two rusty pannikins were close at hand and fragments of skeleton on the floor; these consisted of a skull, vertebrae, and some long bones. On the bed were the bones of a hand, and a number of land crabs scuttled about. The floor was covered with sea-birds’ eggs, and many more were found packed and salted in wooden boxes. Some empty cruet bottles were found near the eggs and a box containing papers which showed him to be a Dutchman; he had served in the militia. The medical officer was able to determine from an examination of the skeleton that it belonged to a lad under twenty years of age. In another hut was found the body of an old negro. The story is clear enough. The well-built hut showed that the men had come prepared to stay a while. The empty boxes showed that food had been at one time abundant; then provisions ran short. The men subsisted for a time on sea-birds’ eggs and water was apparently plentiful. Men cannot live long on eggs and brackish water; scurvy must occur. This is the secret of the crutch in the cabin. Disease had crippled before it killed this young man.¹ This explanation rests entirely on circumstantial evidence, but evidence so complete and convincing, the reasoning so sound, yet apparently so simple, as to make one exclaim on reading it, Surely this is the way of Zadig! When circumstantial evidence is very complete we are accustomed to deal with the judgment based on such evidence as if it were absolutely proved. Take for example fertilisation of the ovum. We all believe that the union of at least one spermatozoon with an ovum is necessary for the production of a metazoan, but so far as man is concerned the belief is based on circumstantial evidence; no man has ever witnessed the meeting of these two wonderful cells. Knowledge of the matter is entirely based on evidence furnished by observation on low animal forms. Indeed, so little direct evidence is forthcoming on this point that we are ignorant of the position in the genital canal where the meeting occurs. That it may take place as high as the Fallopian tube is proved by the frequent occurrence of tubal pregnancy, but it is very improbable that this is the usual meeting place. Some

¹ The Graphic, Oct. 15th, 1892

glimmerings of light are appearing in this dark passage, and we all feel thankful that the fable in which the flimble of the tube seize and convey away the ovum, much like Mephistopheles runs away with Faust from the stage of the Lyceum Theatre, is rapidly disappearing from the minds of text-book writers.

It is always useful to remember that circumstantial evidence of apparently overwhelming completeness will sometimes lead to mistaken judgments. Dr. Radcliffe Crocker had a very intelligent dog; as it advanced in years its breathing became stertorous on exertion, especially after a vigorous scamper. Auscultation revealed a mitral murmur which was very audible after the dog ascended or descended a staircase, and at times the dyspnoea was a source of great alarm to the dog's friends. In due course the abdomen began to enlarge, dropsy was

Yet at the necropsy three rare lesions were found: each occurring singly would be considered rare, therefore the more extraordinary that the three should be coincident and absolutely independent. The case of this dog illustrates very well the unexpected combinations which render uniform accuracy in diagnosis unattainable. In perfect knowledge is a very fertile source of error. I appreciated this in 1879 when I began to investigate diseases of wild animals at the Zoological Gardens. My first great difficulty was to distinguish between structures which in one animal would be considered normal, but in another decidedly morbid. In many, very many, instances I have kept specimens, obtained from rare animals, several years in order to control the observation by examining other examples of the same species before deciding that I have had to deal with deviations from the normal condition. It would be very easy for

FIG. 4.

The remains of a man marooned on Roncador, in the Caribbean Sea, found by the officers of H.M. gunboat *Partridge*. From the *Graphic*, 1892. (Reproduced, with some modifications of detail, with the permission of the Editor.)

suspected, and at last euthanasia was prescribed and carried out by means of prussic acid. At the necropsy very curious conditions were found. The mediastinum contained a mass of enlarged and partially calcified lymph glands, which pressed upon the left recurrent laryngeal nerve. This explained the stridor and its increase on exertion. The mitral valve was curiously malformed, one cusp being connected with the septal wall by means of thick tendons without papillary muscles. These caused the murmur, for the valve was thoroughly competent. The increase in the size of the abdomen was produced by a large extravasation of blood beneath the capsule of the spleen; this, as ascertained subsequently, was the result of a bite from a neighbour's dog. To the mind of the physician the clinical signs in this case were characteristic of some chronic variety of heart disease.

me to detail instances in which experimenters have fallen into error on account of insufficient acquaintance with the normal anatomy of their subjects.

Let me finish this address by describing an example of a structure normal in one bird, but which would be considered pathological in another of the same kind. The beak of the American pelican (*P. trachyrhynchus*) is surmounted by a horn which is structurally identical with the wart-horn occasionally seen on men and women as well as on birds and beasts. A pathologist, on examining the beak of *P. trachyrhynchus*, would at once conclude that he had to deal with a wart-horn on the bird's beak, and the fact that it is shed in the autumn, when the bird moults, does not disprove the view, because pathological horns in birds are shed during moulting and rapidly reproduced with the feathers. A

close acquaintance with American pelicans shows that this horn on the beak is a constant character, and therefore normal. (Fig. 5.) Another source of much unsound knowledge is the enormous number of incomplete records contained in periodical medical literature. This is particularly obvious when the records rest merely on clinical observation. Lastly, let me advise you, in cases surrounded by great doubt,

FIG. 5.

The American pelican, showing the horn on its beak.

to be careful and to reserve your judgment. What is extremely dubious to-day may be clear and certain to-morrow. In forming a judgment keep to the facts (when inference is concerned there is no certainty), and never let the reasoning outstrip the evidence.

HEART PAIN AND SENSORY DISORDERS ASSOCIATED WITH HEART FAILURE.

By JAMES MACKENZIE, M.D. EDIN.,
HONORARY MEDICAL OFFICER, VICTORIA HOSPITAL, BURNLEY.

IT is possible to enumerate a great number of symptoms that are induced by failure of the heart. Individual cases may present a greater or less number of these symptoms, and it is rare that two cases present exactly the same features. As the evidence of heart failure may be exhibited in a disturbance of the functions of organs more or less remote from the heart itself, it is frequently difficult to appreciate the relative value of such evidence. By no organ are the symptoms so varied in site and in character as those exhibited by the nervous system; yet when a clue is obtained as to the meaning of the various manifestations, no series of symptoms point more conclusively to the seat of mischief. Heart failure to an extreme degree may be present, and no physical signs may be discovered in pursuing the usual methods of exploration, while, if the sensory phenomena be carefully studied, evidence of great value may be at once forthcoming. While the symptoms of heart failure evoked by the nervous system are not limited to the sensory nerves, it will mainly be the sensory disorders with which this paper will be concerned. The term "heart failure" will be employed in preference to heart disease, inasmuch as the symptoms are sometimes evoked in cases where there is no demonstrable cardiac lesion. The failure of heart power may be, however, the undoubted cause of their appearance, this failure and its accompanying symptoms frequently being evanescent.

Pain.—The sensory disorders vary in different individuals, and occasionally in the same individuals at different times, both in character and situation. I have not made much out of the study of pain in regard to its degree and the other characteristics occasionally employed in describing it, nor do I find its association with the sense of impending death either of universal occurrence or peculiar to affections of the

heart. What I have been careful to note is its mode of onset, its site, and its radiation. In the first examination of the patient one rarely gets a satisfactory account of these points. It has been my custom to request the patient to note carefully these points in subsequent attacks. The account then given is very trustworthy, and can often be verified by the presence of other symptoms.

Hyperæsthesia.—The most important of these other symptoms is a state of exalted sensibility—a hyperæsthesia of the skin and certain subcutaneous tissues. Although the hyperæsthesia when present often occupies the area in which pain is felt, it often happens that there is no hyperæsthesia of any tissue, even when the pain has been of the most violent character. The demonstration of the areas rendered hyperæsthetic can usually be readily effected. The area of cutaneous hyperæsthesia can be determined by stroking with a pin's head, approaching the tender area from the surrounding healthy skin. Sometimes the skin is not found tender by this method of stimulation, and then it can be demonstrated by lightly pressing small folds of skin between the thumb and forefinger. When the skin is hyperæsthetic to the pin-head it is also tender to this latter method of stimulation. The areas mapped out on any individual exhibiting both are not extensive, the area revealed by lightly pinching being somewhat more extensive, but embracing the area revealed by the pin-head method. Nor can the borders be exactly delimited by either method, as the areas are variable in their sensitiveness at the margin. This variability in the areas elicited by these two methods is not peculiar to the hyperæsthesia of visceral disease, but may also be demonstrated in the hyperæsthesia occasionally present in herpes zoster. The subcutaneous fascia, glands, and muscles can be demonstrated to be hyperæsthetic by lightly pinching, first testing that the skin covering them is not hyperæsthetic.

The association of the visceral with the sensory nerves.—When the nerves supplying the areas of skin and the muscles thus demonstrated to be hyperæsthetic are considered, and their root origins determined, it will be found that their nerve centres are in close association with the nerves supplying the organ whose disease has originated the sensory phenomena. It follows, then, that if the centres of the nerves supplying the viscera were known, the organ affected could be recognised by the painful and hyperæsthetic regions in the external body wall. The only conceivable explanation for the presence of these sensory disorders is that a stimulus is conveyed by means of the nerves supplying the organ to the centres of the spinal nerves. This stimulation induces the pain, &c., which is referred to the peripheral distribution of the nerves whose origins are affected. These centres probably being in a state of exalted sensibility stimuli applied to their peripheral distributions produce a sensation of greater intensity, and which we call "hyperæsthesia." This view receives support from the fact that the stimulus transmitted from the organ at fault excites other nerve centres which produce the phenomena characteristic of their function, as an increased secretion in the case of the nerves supplying the salivary glands in Cases 1 and 15.

The nerve-supply of the heart.—The heart receives its nerve-supply (1) from its intrinsic nervous mechanism, (2) by means of the vagus, and (3) by means of the sympathetic. The first of these concerns us here only in a secondary manner. No sensory disorders are evoked by these nerves. It is highly probable that abnormal excitation of these nerves can be recognised by certain characteristic irregularities of the heart's action. In the further course of this paper these will be left out of consideration. The vagus supply at its origin is brought into relationship with certain nerves distributed to the external body wall. The most important of these is the spinal accessory nerve. In the distribution of this nerve to the sterno-mastoid and trapezius muscles a striking and an instructive field of observation is provided for the examination into areas reflexly rendered hyperæsthetic. From this nerve the sensory disturbance may extend to the nerves, associated with the spinal accessory in its supply to these muscles—viz., the second and third cervical,—and may thence extend to their cutaneous distribution in the head and neck. The sympathetic supply of the heart is associated with the spinal nerves from the lower cervical and upper dorsal regions of the cord. It is in the region of distribution of the spinal nerves from the seventh cervical to the fifth dorsal that the sensory abnormalities associated with heart failure are most frequently and most characteristically distributed. As the area involved in this distribution includes

the arm and hand, there is provided a field of observation so peculiar that many inferences can with safety be drawn from the results obtained which would otherwise be impossible if the areas were limited to the trunk.

Cutaneous distribution of the cervical and upper dorsal nerves.—In order more fully to appreciate the significance of the hyperæsthetic fields in heart failure it will be advisable to bear in mind the distribution to the skin of the nerves implicated. The cervical nerves from the second to the fourth supply the skin of the back of the head, the neck, and shoulders. They also descend on the front of the chest at least as low as the third rib, where they overlap with the second dorsal supply (Fig. 7). The fifth and sixth cervical nerves are distributed in the arm in an area roughly described as the outer half of the upper arm, the radial half of the forearm, and part of the thumb (Fig. 8). The seventh cervical is distributed to the hand and fingers, the eighth also to the ring and little fingers, to the ulnar borders of the hand, and with the first dorsal supplying the ulnar half of the forearm. The second and third dorsal are distributed on the inner half of the upper arm, axilla, and chest, meeting and overlapping the fourth cervical, as already stated. (Fig. 1.) The fourth and fifth dorsal are distributed to the chest, the latter descending as low as the upper part of the epigastrium. It must be borne in mind that each spinal nerve practically divides into three parts after the junction of the posterior and anterior nerve roots—viz., a posterior, a lateral, and a ventral. It is the lateral and ventral divisions that are involved in the supply to the arm, the posterior divisions being distributed to the skin of the back. Thus, then, with the exception of these posterior divisions, the nerves from the fourth cervical to the second dorsal are distributed to the arms. The second dorsal nerve (occasionally also the first) does send branches to the front of the chest. There is thus an interesting test provided in considering the distribution of any sensory abnormality—pain or hyperæsthesia—that arises in the chest. If it affects a series of nerve centres in succession it will not pass up the chest and over the clavicle, but will descend on the inner aspect of the arm to the ulnar border of the hand (Figs. 1, 2, and 5). In like manner pain &c. arising in the neck, and produced by stimulation of a descending series of cervical nerve roots, will proceed down the chest for only a short distance, and then be deflected down the outer portion of the upper arm to the radial border of the hand (Fig. 6). In the following study of a series of cases it will be found that this view is exactly carried out.

Herpes zoster and sensory disorders.—Several years ago, while studying these sensory phenomena, I was struck by the resemblance of the situation occupied by the eruption in herpes zoster to the situation of the pain and hyperæsthesia in certain cases of visceral disease. As a rule the eruption in herpes zoster has hitherto been described only in relation to the peripheral nerves; but, inasmuch as these nerves are usually composed of fibres from more than one nerve root, no very satisfactory information has resulted. Recognising the fact that herpes zoster is usually due to an affection of the root of the nerve (probably the ganglion on the posterior root), the areas in which the eruption &c. occur become intelligible and instructive. Frequently there is evidence that more roots than one are affected, but these are generally neighbouring roots. It is difficult to say when one nerve root only is affected. There are other symptoms present besides the herpes zoster that help to complete the picture and to indicate the direction in which neighbouring nerve roots are distributed to the skin. The most important of these other symptoms are pain and hyperæsthesia, and when the eruption is scanty or absent it is difficult to decide whether these phenomena are not due to some visceral disease; indeed, this resemblance is so great as to lend countenance to the view of the possibility of visceral disease causing herpes, and I have collected a few cases which seem to be corroborative. At present I shall merely offer for comparison the similarity of the areas affected. Dr. Head has independently pursued the same line of inquiry with excellent results.

To elucidate the various points involved in the study of the sensory disorders associated with failure of the heart I shall give a brief record of a few of the cases in which I have observed these phenomena. I have collected records of a very large number of cases and several of those here given are quite exceptional, but as they fill up gaps and enable me to complete the picture they are invaluable. For the sake of brevity, only the points that are material to the

subject in hand are included in the records of the cases here given. In most of them I have full, and even voluminous, notes of the condition of the patient at different times. In some respects an apology is necessary for the incompleteness of the post-mortem examinations. As the cases were with one exception those of private patients considerable difficulty was usually experienced in getting permission to have a necropsy. When one was held it was usually conducted under great difficulties. Three of the cases given here have been published in full elsewhere, and I recapitulate them because of their great importance and because of the rarity of post-mortem demonstration as to the nature of the heart lesion.

CASES ILLUSTRATIVE OF THE AREAS MOST COMMONLY AFFECTED.

CASE 1.—A man aged fifty-eight years, of gouty diathesis, complained of pain induced often by the slightest exertion, which arose in the left breast, passed up to the armpit, and extended down the inner surface of the left arm to the little finger. During an attack an abundant flow of saliva took place into the left side of the mouth. Careful and repeated physical examination revealed no cardiac abnormality. The left chest in front (skin and subcutaneous tissue), from the middle line to the nipple line, was at times very tender to the slightest pressure. There was excessive tenderness on pressure over the second left rib in the nipple line and over the second dorsal vertebra. The patient died suddenly, and, on post-mortem examination, the heart was found to have ruptured, the pericardial sac being full of blood. There was a small aneurysm the size of a marble in the wall of the left ventricle, where the ventricular cavity was separated from the pericardial sac by a thin wall consisting only of pericardium and endocardium. In this thin wall there was a narrow slit. The coronary artery was very atheromatous. The external anterior thoracic nerve was found to be lying under the place, over the second rib, that had been so tender to pressure during life.

CASE 2.—A man aged fifty-nine years complained of pain and shortness of breath on walking a short distance. The pain arose in the centre of the chest and extended out to the left and down the inner surface of the left arm. There was tenderness to pressure from the second to the fourth ribs on the left side in the nipple line. There was a slight increase in the area of heart dulness; otherwise there was no cardiac abnormality. The patient died with loss of speech, slight paralysis of the right cheek and right side of the tongue, and Cheyne-Stokes respiration. At the post-mortem examination the heart muscle was found to be soft and flabby, and on microscopic examination showed well-marked fatty degeneration. There were slight atheroma of the aorta and slight thickening of the cusps of the mitral valve. As in the previous case, the internal anterior thoracic nerve was found to be lying over the ribs where there had been tenderness to pressure during life.

During the lives of these two patients I made repeated observations of the sensory phenomena above alluded to and I recapitulate them here as they demonstrate the symptom present in a very large number of patients. I could, indeed, recite other cases where the hyperæsthesia was more striking; but I have not been able to obtain such convincing proof of the lesion of the heart as in these two cases. The pain here occupied without doubt the region of distribution of the spinal nerves, from the fourth dorsal to the seventh or eighth cervical. The area of pain was practically that of the pain and hyperæsthesia as mapped out in Fig. 5, and corresponds with wonderful accuracy to the distribution of the eruption I observed in a case of herpes zoster, and which is repre-

FIG. 1.

Distribution of the eruption in a case of herpes zoster, agreeing with the area in which pain was felt in Cases 1 and 2, and with the area of hyperæsthesia in Case 14 (Fig. 5).

mented in Fig. 1. In another case of herpes zoster, in which there was only a scanty eruption on the chest in front, the

pain was wont to radiate with agonising severity down the inner surface of the left arm and the ulnar border of the forearm to the little and ring fingers.

Radiation of pain from the hand to the chest.—In the great majority of cases the pain arises in the chest and radiates into the arm. In rare cases the pain may start in the arm and radiate to the chest. This had been noted by Walsh when he supposed that "the brachial pain played the part of an aura"; but as we now know the relationship of the nervous supply to the parts affected a more reasonable and fitting explanation is supplied.

CASE 3.—A man aged sixty-six years was first seen by me in September, 1893, with Dr. Dickey of Colne, suffering from asthma, an enlarged irregular heart, and albuminuria. I saw the patient again on March 9th, 1894. He had had on that day two uræmic convulsions. His left forearm was wrapped up in flannel because of the severe attacks of pain which kept recurring at intervals. The pain commenced in the arm and radiated to the chest. The pulse was firm and hard, 104 per minute; the respiration was laboured (28). The heart was enlarged to the left, and there was a well-marked triple heart sound. There was a large quantity of albumen in the urine. The patient was asked to note particulars in regard to the pain. I saw him again on the following day. He had had several attacks of pain, which began in the left little finger and extended with great severity up the ulnar border of the forearm and the inner surface of the arm to the front of the chest. He had now developed well-marked Cheyne-Stokes respiration, and the pulse had become very irregular. The patient died two days later.

Irregularity in distribution of the nerves and of the pain.—In the foregoing cases the pain has faithfully followed the course of the distribution of the spinal nerves. There is no doubt that certain variations occur in the distributions of the nerves in different individuals, and cases arise that do not conform to the usual description. In the somewhat schematic description of the distribution given above the order of distribution of the nerves below the fourth cervical was down the outer surface of the arm to the thumb and fingers, and up the inner surface of the arm. In the following case the course pursued by the pain was not altogether in accord with this description.

CASE 4.—A man aged fifty-two years had been under observation at frequent intervals for four years. His chief and almost only complaint during that time had been of a pain induced by exertion. At times the pain had been so easily excited that he had had to keep quiet in bed for several days, and then he would be comparatively free for some time. He was a pale, thin man, whose countenance had the drawn lines expressive of great suffering. I had many times made a careful physical examination of his heart, but could detect no abnormality except the presence of a venous pulse of the auricular type and on two occasions a single intermission in the pulse beat. The pain was described invariably as arising in the left chest and extending to the armpit, down the inside of the arm and the ulnar border of the forearm to the wrist, whence it extended across the palm to the thumb, leaving the fingers unaffected, but causing great aching in the thumb.

FIG. 2.

The shaded area represents the situation of pain in Case 4.

On Feb. 8th, 1894, he again consulted me, complaining, in addition to the constant recurrence of the foregoing pain, of a soreness and tenderness of the scalp. The nature and extent of this I could not well determine. In the month of March this soreness of the scalp had developed into severe attacks of headache, readily induced by exertion, but also coming on when quite still. This headache started always at the left eyebrow, and might remain fixed there, but usually spread to the back of the head, including both sides. There was no sensory abnormality of the skin, but there was tenderness on

pressure over the supra-orbital nerve. This headache became so violent that the patient had to keep to his bed, and finally he became comatose, developed Cheyne-Stokes respiration, and died on March 27th. Permission was obtained to examine the heart only at the post-mortem examination. The heart was very flabby, and the walls of both ventricles were soft and friable. There was well-marked atheroma of the coronary arteries. In many places the arteries and their branches were calcified. Microscopic examination of the cardiac muscle (left ventricle) revealed fatty degeneration.

Although there were no other sensory phenomena in the chest and arm except the pain it was so well and repeatedly defined by the patient that there was no difficulty in tracing out its course. Fig. 2 is the sketch I made during one of the many examinations, and its accuracy was corroborated by the patient, who was an educated and intelligent man. I was very much puzzled at this distribution and made on that account the more sure of the facts of the case. Six weeks after his death my friend Dr. Harwood showed me a case of herpes zoster under his care in whom the eruption on the arm exactly corresponded to the distribution of the

FIG. 3.

Distribution of the eruption in a case of herpes zoster, where the eruption corresponded to the pain described in Case 4.

pain in Case 4. Fig. 3 is from a photograph of the patient with the herpes zoster taken by Dr. Harwood.

In the foregoing cases the pain has appeared in an area supplied by nerves from the fourth or fifth dorsal to the seventh cervical nerves. The pain may, however, be limited to an area supplied by a portion of one or at most two of these nerves.

CASE 5.—A man aged thirty-eight years complained of a pain which on the day previous to examination seized him for the first time with excessive violence. The patient indicated the site of pain as across the left chest, under the nipple. A careful examination only revealed a slight enlargement of the heart dulness and a slightly increased area of dulness between the second costal cartilages. While out walking on the day following this examination the patient was again seized with the same pain and died in two hours from the beginning of the attack. On post-mortem examination there were found to be slight enlargement of the heart and a suspicion of dilatation of the first part of the aorta, no other lesion being discernible.

CASE 6.—A woman aged sixty years complained of pain of agonising severity limited to the ulnar border of the left forearm. The pain was induced by exertion. The left side of the chest was tender to pressure, and pressure over the second left rib in the nipple line and over the second dorsal vertebra was very painful. The pulse was full, soft, quick, and regular; the arteries were atheromatous, and there was a slight enlargement of the heart's dulness. The second aortic sound was markedly accentuated. The patient died with symptoms of heart failure, dyspnoea, dropsy, &c. At the post-mortem examination there were found marked atheroma and calcification of the coronary arteries, extensive chronic fibrous myocarditis, and no signs of fatty degeneration.

CASE 7.—A woman aged fifty-two years complained of pain that came on with terrible severity across the upper part of the epigastrium and round under the left breast. While the pain was present perspiration poured from her. These pains had begun a year previously, and at first were not very severe. Three weeks ago they had returned with great severity. They always came on either during or immediately after bodily exertion. The pain lasted from ten minutes to one hour. She was very short of breath and suffered from a severe spasmodic cough. The patient was big, fat, and florid. The feet and legs were swollen. It was impossible to define the limits of the heart's dulness because of her obesity. The second sound was markedly accentuated at the base; otherwise the heart sounds were normal. There was tenderness on pressure over both second ribs in the nipple line. The upper

part of the left sterno-mastoid was tender on pressure, as also a point immediately above the middle of the left scapular spine. There was no albumen in the urine. The patient was requested to inhale a few drops of nitrite of amyl during an attack, and after a time reported that it immediately and invariably relieved her.

In Case 6 the pain was doubtless limited to the highest nerve centre, whose fibres are associated with the sympathetic supply of the heart; while in Case 7 the pain affected the lowest nerve centre, probably the fifth dorsal. In such cases as Case 7 it is somewhat difficult to be absolutely sure that the pain is cardiac in origin and not stomachic. If all the circumstances of the case be taken into consideration—the pain induced by exertion, its association with sensory abnormalities in regions characteristic of heart failure, dropsy, shortness of breath, &c.—I think there is little doubt of the accuracy of the diagnosis. It does happen, however, that one sometimes has great difficulty in differentiating between the two forms of pain, and that this complication is likely to arise will be realised when it is borne in mind that dyspepsia is often induced by failing circulation, as in the following case.

CASE 8.—A woman aged fifty-four years suffered from attacks of pain in the left chest and abdomen. She had had rheumatic fever twenty-eight years previously and had had numerous attacks since. She had five children. The heart was enlarged, the apex beat being in the sixth interspace one and a half inches beyond the nipple line. There was a rough, loud, systolic murmur at the apex propagated into the axilla, and a murmur, also systolic in time, was heard at the base and mid-sternum, but of a softer character. There was no cutaneous hyperæsthesia elicited by stroking with a pinhead, but when the skin was lightly pinched there was distinct tenderness in the front of the left chest (Fig. 4), and the deeper tissues were tender over a somewhat larger area, while pressure over the second, third, and fourth ribs was particularly painful. At times the patient could scarcely move across the floor without inducing a violent attack of palpitation and severe pain. The pain was usually situated about the level of the second and

FIG. 4.

The shaded area on the chest represents the field of hyperæsthesia from heart failure, that on the abdomen the area of hyperæsthesia due to dyspepsia. (Case 8.)

third ribs. It began in the middle line and radiated across the chest, almost reaching the axilla. Occasionally the pain was lower down, arising in the upper part of the epigastrium and radiating round under the left breast. The chest felt as if held in a vice when this pain came on, and she felt as if she was about to die. She suffered much from indigestion and had often severe pain after taking food, which was relieved by eructation of gas. The pain then was lower in the epigastrium, in the region of a tender spot, which she pointed out, and which I found to be distinctly hyperæsthetic, as in Fig. 4.

Pain limited to the right side.—In these cases, so far, the pain and sensory phenomena have been mainly located on the left side. Although extension of the pain to the right side is by no means infrequent, yet its limitation to the right side alone is in my experience very rare. The following is the best example of such limitation.

CASE 9.—The patient was a man aged twenty-four years. I had attended him four years ago for rheumatic fever, in which there was developed endocarditis, leaving him with a damaged mitral valve. He kept fairly well until the autumn of 1893, when he began to get short of breath and suffered from hæmoptysis. He recovered from this attack, and on Feb. 26th, 1894, I saw him again. He was in bed, and suffered from great pain situated over the lower part of the right scapula and the inner surface of the right elbow-joint. There were an irregular pulse, great enlargement of the heart's dulness, a pre-systolic murmur, pulsation of the velus of the ventricular type,

and œdema of the lungs. During the night he expectorated a large quantity of blood, and obtained relief from the pain. He died on March 4th, and on post-mortem examination I found the tricuspid orifice to be widely dilated, the mitral orifice narrowed and its margins hard and calcareous, and the bases of the lungs deeply congested, being in some parts solid. The location of the pain in this case is peculiar, but will be exemplified to some extent in Cases 10 and 11.

Bilateral distribution of pain &c.—The manner in which the pain and other symptoms have spread in the foregoing cases is not at first quite clear. It is unusual that the whole distribution of any given nerve is affected. More commonly neighbouring areas of a portion only of the distribution of a number of nerves are affected. Thus in most of these cases the anterior branches have manifested the sensory abnormalities, while there has been little or no affection of the posterior branches. Symptoms may, however, also spread to the opposite side of the body, but in such cases there is a tendency for the symptoms to be manifested in corresponding areas. The pain itself is not so severe, and areas occupied by the pain and hyperæsthesia are not so extensive on the right side as on the left. This tendency to bilateral distribution of the sensory phenomena in visceral disease finds its counterpart in the tendency to bilateral distribution of the eruption in multiple herpes zoster. In the course of a pretty extensive inquiry into the distribution of the eruption in herpes zoster I was struck by the fact that when the eruption was multiple in the majority of cases there was a distinct tendency to a bilateral distribution of the eruption, one side being usually more affected than the other. This observation has been verified in a number of cases that have come under my own observation, and in one case where a scanty eruption occurred on the face, chest, and thighs the eruption was exactly symmetrical. The following case of the occurrence of pain of heart origin illustrates this tendency to the bilateral distribution of the pain.

CASE 10.—The patient was a man aged fifty years. Ten years previously I had attended him for an attack of fainting. For seven or eight years he had had gouty contractions of the right ring and little fingers and tophi in his ears. Two years ago, while in church, he was seized with severe pain on the inner side of the left forearm, near the elbow. While the pain lasted perspiration poured off him. He consulted me on the following day, but I could detect no cardiac or other abnormality. Some months later I observed a transient irregularity in the pulse during a slight feverish cold from which he was suffering. After this he appeared to be quite well and was able to take active exercise without discomfort. On March 11th, 1894, he was again seized with the pain and noted its exact site. It was situated in exactly identical places on the inner side of both forearms, near the elbow. The pain held him for nearly an hour. Next day he consulted me, and I found that the heart was extremely irregular in its action. The patient also, from being a bright, lively man, had become haggard and careworn, and oppressed with an indefinite sense of discomfort. He remained in this state for ten days, when his pulse again became quite regular and the sense of oppression left him. Since that time he has continued in good health.

CASE 11.—A woman aged fifty-seven years had been under my care eight months previously suffering from heart failure with shortness of breath and palpitation. She improved under treatment, but while I was writing this paper she again consulted me for a violent pain that seized her on the inner surface of the left arm and extended behind over the left shoulder-blade and right shoulder-blade, extending sometimes round over the right breast. The pain came on with exertion. The pulse was full, quick, and regular, and the arteries were atheromatous. The apex beat was in the fifth interspace, two inches outside the nipple line. There was a short tricuspid systolic murmur. The upper four dorsal vertebrae were tender on pressure, and there was a spot tender on pressure above the left scapular spine. After the examination and while dressing, the patient being somewhat excited, the pain struck with extreme severity over the lower part of the right scapula. There was no hyperæsthesia. The pulse was quickened and the face flushed, and she was bathed in perspiration. She lay down and inhaled a few drops of nitrite of amyl, and experienced complete relief in a few minutes. The pain in this attack did not radiate, and she stated that sometimes it was limited to one part. She never experienced such rapid relief in any other attack.

It will be observed that the pain in the attack I observed in Case 11, and the situation of the pain in the right arm in Case 10, are the places where the pain was felt in Case 9. The area in the right arm was also the seat of pain in Case 14, which was found to be hyperæsthetic. The association of these corresponding areas on the two sides of the body is exemplified in a case of herpes zoster I had under observation. A lad fell on his head from a cart and felt stunned for some minutes after. A few days later a herpetic eruption occurred on the back of his neck, affecting both sides almost to the same extent. On the back of each elbow there was also a crop of vesicles identical in situation. This distribution of the phenomena on both sides of the body will be further exemplified in some of the following cases.

Symptoms in the head and neck.—So far the symptoms that have been referred to are those in association with the sympathetic nerve-supply. In carefully examining the patients I became aware of distinct sensory abnormalities in

other fields. The most conspicuous of these was tenderness on lightly pinching the sterno-mastoid and trapezius muscles. That the muscles themselves are tender admits of no doubt. The skin and subcutaneous tissues may be pinched without evincing any abnormal tenderness, but, when the muscle substance is pinched, tenderness, sometimes exquisite, is evoked. Finding the sterno-mastoid and the trapezius so frequently tender, and having regard to the nerve-supply, the spinal accessory, with its known association at its origin with the vagus, led me to consider that the transmission of the irritation to the spinal accessory was from the heart by the vagus. While the abnormal sensitiveness of the sterno-mastoid muscle and of the trapezius are the most constant phenomena, there are frequently sensory disorders in other places. Thus pain may be felt in the neck, in the scalp, and in the jaw. Hyperæsthesia may also be present in these areas. The significance of these areas as demonstrating the connection of the nerves so affected at their centres with the vagus affords an interesting study; but as the anatomical relationship is as yet far from clear the discussion would be somewhat speculative and would be rather extraneous to the conception of this paper, which is intended to be a clinical exposition of the sensory phenomena in heart failure rather than an inquiry into how these occur. As a rule, the sensory phenomena occurring in the head and neck are associated with those occurring in the upper dorsal and lower cervical nerves. As a matter of routine, in many cases it is my custom to press over the second left rib in the nipple line, over the upper dorsal vertebrae, pinch the left sterno-mastoid muscle, and press upon the trapezius immediately above the spine of the scapula. If sensory phenomena are present they are usually manifested in one of, if not in all, these areas. In some cases all are extraordinarily sensitive, and, excepting some obscure pains, no other sensory disorder may be present. The following case had only slight evidences of sensory disturbance, limited to the two muscles.

CASE 12.—A man aged thirty-two years complained of shortness of breath and swelling of the legs. There was marked double pulsation in the veins of the neck, the heart was much enlarged, and there was present a loud diastolic aortic murmur. There was tenderness on pressing the left sterno-mastoid and the trapezius muscles, the latter not being quite so sensitive. After a few days in bed this tenderness quite disappeared. The patient appeared to be progressing favourably when he suddenly died. At the post-mortem examination the aortic valves were found to be thick and shrunken, with a long vegetation attached to one cusp. The mitral and tricuspid orifices were greatly dilated.

The symptoms present in the head and neck are often associated with those affecting the chest and arms. The symptoms are generally more conspicuous in one or other region, but the severity varies in different individuals and even in the same individuals at different times.

CASE 13.—A man aged sixty-two years complained of great pain striking into his chest and behind his ears when walking. Thus in going to his work he was wont to allow seven or eight minutes to walk to the station, but now it took him over half an hour, as he had to stop on account of the pain every fifty yards. After accurately noting the pain he described it as arising in the left breast, extending across to the right breast, seizing him in the neck, and extending up behind the ears, where it held him with great severity. In showing me the situation he laid the fingers of both hands over the insertion of the sterno-mastoid into the mastoid process. On one occasion the pain extended from the breasts to the armpits and down the inside of each arm to the elbow. The pulse was full and regular and the arteries were tortuous and atheromatous. The lungs were emphysematous and covered the heart. There was tenderness on pressure over the second left rib in the nipple line and over the left sterno-mastoid and trapezius muscles. The right sterno-mastoid was also slightly tender at the upper part.

The manner in which these symptoms first appear in individual cases and the way in which they spread afford a highly instructive view of the various regions allied with the heart in its nerve-supply and give a clue to the unravelling of many obscure phenomena. The next two cases have been under my close observation for several years. As Case 14 presented features of extreme interest apart from the sensory phenomena, I have spent much time in the study of the condition of the patient. In this manner I became acquainted with the first appearance of the sensory phenomena associated with the heart failure in her case, and have watched them gradually develop into the condition in which they are at present.

CASE 14.—A woman aged thirty years had been under almost constant observation for three years, as she presented features of extreme interest. There was distinct evidence of stenosis of the mitral and tricuspid valves, and there was present marked pulsation in the veins and in the liver. I have elsewhere described these phenomena at length. Eighteen months ago she came to me complaining of a disagreeable smarting pain in the left axilla. I examined her, and found the skin in the axilla and adjacent parts of the thorax to be extremely hyperæsthetic. A few days later she began to suffer from slight attacks of pain in the left breast and down the inside of the left arm; and then, on examination, I found that the hyperæsthesia had

extended and occupied an area similar to that shaded on the left side of Fig. 5. These attacks of pain became so severe on the slightest exertion that she was forced to lay up. Since that time she has at different periods suffered from severe attacks of pain, and I have occasionally found, when she was very ill, the hyperæsthesia embrace nearly the whole of the left chest and inside of the left arm, and also a portion of the front of the right chest. The left sterno-mastoid and trapezius also became very sensitive. Latterly she has been better, and when I last examined her on May 25th, 1894, she complained of a disagreeable pain located on the inner side of the right forearm. I examined the place and found it to be extremely hyperæsthetic. There was also present the hyperæsthesia as represented in Fig. 5, which was mapped out on this visit.

FIG. 5.

The shaded area on the left chest and arm represents the area of cutaneous hyperæsthesia in Case 14.

CASE 15.—A woman aged seventy years had been under my care for over ten years. Seven years previously she had had a long illness of great obscurity, characterised by excessive prostration, with pain under the left breast. Two years ago she consulted me for a pain of much severity that struck her across the chest on the slightest exertion. A note taken at that time described the face as being pale and distressed looking. The pulse was full, soft, and regular. The heart was enlarged to the left, and there was a systolic murmur at the base and over the carotid. When the pain came on it struck her under the left breast and between the shoulder-blades. There was an area of hyperæsthesia of the skin over the left chest from the third to the sixth ribs and from the left

FIG. 6.

The shaded areas represent the distribution of cutaneous hyperæsthesia in Case 15. The subcutaneous tissues of the whole of the left side were also abnormally tender.

border of the sternum to the anterior axillary line. There was great tenderness on pressing over both second ribs in the nipple line, over the third, fourth, and fifth dorsal vertebrae, and on pinching the left sterno-mastoid and trapezius muscles. After a long period of rest in

bed she improved. A year ago, in addition to these symptoms, there was a large patch of cutaneous hyperæsthesia on the left side of the neck, and when I last examined her (May 27th, 1894) this had extended, affecting the whole left side of the face and neck and the arm in the characteristic manner depicted in Fig. 6, while the subcutaneous tissues of the whole of the left half of the body were abnormally tender. There was also a band of cutaneous hyperæsthesia round the left chest.

The area here hyperæsthetic may be instructively compared with the distribution of the eruption in the two cases of herpes zoster represented in Figs. 7 and 8.

FIG. 7.

Distribution of the eruption in a case of herpes zoster, affecting, probably, the third and fourth cervical nerves.

The distribution of the hyperæsthesia down the inside of the arm in visceral disease is very common, but its distribution down the outer side, as in Case 15, is in my experience very rare. That this region may exhibit sensory disorders would seem to be possible from the study of the following case.

CASE 16.—A woman aged forty-five years had been under my care at intervals for the last ten years. She suffered from great enlargement and very irregular action of the heart. Seven years ago she was laid

FIG. 8.

Distribution of the eruption in a case of herpes zoster, affecting, probably, the fifth and sixth cervical nerves.

up for a long time with extensive dropsy. For the last few years she had suffered at intervals from great shortness of breath on the slightest exertion. On March 29th, 1894, she complained of a pain of great severity that struck into the right shoulder. I asked her to note carefully its exact site and character, and four days later she told me it always came on with exertion or immediately after, that it began in the middle of the side of the right neck, and extended down over the shoulder and down the outer surface of the arm to the elbow. Once or twice she had felt a slight pain at the same time under the left breast, and, rarely, a sense of pressure just below the left shoulder blade. She feels very helpless when the pain comes on. There is no hyperæsthesia, but she says that after an attack of pain the side of the right neck is very tender to pressure. She is extremely weak and short of breath, and the feet and legs are swollen.

Attacks of depression without pain.—A frequent accompaniment of the pain is the sense of depression, which is sometimes so great as to give the patient the feeling of impending

death. In individual cases the attacks of pain may occur without these sensations, while at other times it is a very distressing feature. Vague sensations of great discomfort are often present, associated with attacks of palpitation and transient irregularities of the pulse. Very rarely there may be met with cases that present typical attacks of intense depression with no symptoms of pain.

CASE 17.—The patient, a thin, spare man, aged forty-eight years, with a faint flush on his cheeks, complained of great weakness and shortness of breath. Since childhood he had suffered much from cold hands—some of the fingers occasionally going quite white and cold. When walking he is suddenly seized with attacks of great weakness, so that he has to clutch for support or he would fall to the ground. A sensation of sinking is then felt at the pit of the stomach, and a sense of depression comes on, which he describes as something fearful, and he feels as if he would die. The first attack occurred when he was twenty-three years of age after a very long period of excessive exertion. He did not have another attack for twelve years. Latterly he had been having as many as four in one week. The pulse is quick, regular, and very small. There is never any pain and there is no hyperæsthesia. The heart is slightly enlarged, and there is a marked diastolic murmur heard over the lower half of the sternum.

The spreading of the pain and hyperæsthesia.—There are a considerable number of other points which I would have liked to have illustrated, but space forbids more than a brief reference to them. Thus when a supposed stimulus reaches the nerve centres it may affect different portions, and then the symptoms may be exhibited in the distribution of the anterior, lateral, and posterior divisions of the nerve, or may spread to the corresponding areas of neighbouring nerves, or even to the corresponding areas on the opposite side of the body. On the other hand, it may affect the whole of one side of the body. According to a recent writer, hyperæsthesia of one half of the body is a rare thing. Were these sensory disturbances more thoroughly studied it would be found to be far from infrequent. It will be observed from the selection of cases that the cutaneous hyperæsthesia is more readily developed in females than in males. The occurrence of hyperæsthesia with visceral disease in hysterical subjects is very confusing, and I had intended to have given some illustrative cases, but as these fully confirm the description given by Dr. Head it is scarcely necessary.

Vaso-motor and pilo motor reflexes.—So far the symptoms on which this method of studying is based are purely subjective. There are, however, some symptoms that we can study independently of the patient. If a pinhead be drawn firmly down over the skin of the trunk of a person whose body is warm a series of changes will result in the skin. Thus the temporary pallor will give rise to a blush extending half an inch on either side of the scratch. In a few seconds this will disappear, and the line of the scratch will become raised. If the pinhead has traversed a hyperæsthetic area these phenomena will be witnessed above and below the hyperæsthetic area, but over the hyperæsthetic area they will frequently not be produced. A localised goose skin often follows in the track of the scratch, but sometimes it may spread and occupy the whole of the hyperæsthetic area. These phenomena do not appear in every case, though I have been able frequently to demonstrate them; but my results, although very interesting and instructive, do not justify me as yet to do more than call attention to them as corroborative of the purely sensory symptoms.

Differential diagnosis.—One of the things that influences me in thus emphasising the sensory phenomena exhibited in heart failure is that the symptoms so produced may be exhibited with affections of other organs, and the dependence of the disease of these organs on the heart failure may be obscured or lost sight of. Thus many cases of chronic bronchitis are undoubtedly due to heart failure; but, unless a valvular murmur or some irregularity is present little regard is paid to it. Now, if these sensory symptoms be studied, very frequently they will be so striking as to leave little doubt as to the primary source of the mischief. But it may be asked, Do not other diseases give rise to sensory phenomena that are supposed to be characteristic of heart failure? I think not. I have made careful examination of typical cases of asthma, bronchitis from tuberculous causes, phthisis, pleurisy, &c., but have not found any difficulty in differentiating them. In phthisis, for instance, the whole chest may become hyperæsthetic, but I have never found it pick out the areas peculiar to the heart. Rarely at menstrual periods the breasts become tender, but then it is both breasts that are affected. On the other hand, respiratory affections induced by heart failure, where the heart ailment was demonstrable by murmur, increased size, and irregularity, have presented sensory phenomena identical with those cases

where the respiratory affections have been induced by heart failure, but where the sensory phenomena were the only reliable guides to the heart affection.

Burnley, Lancs.

A CASE OF ABDOMINAL ANEURYSM TREATED BY LAPAROTOMY AND THE INTRODUCTION OF WIRE INTO THE SAC; DEATH.

[WITH COLOURED ILLUSTRATION.]

By W. F. STEVENSON, M.B., B.Ch. DUBL.,
BRIGADE-SURGEON LIETTENANT-COLONEL,
PROFESSOR OF MILITARY SURGERY, ARMY MEDICAL SCHOOL, NETLEY.

A MAN twenty-five years of age was invalided from India for abdominal aneurysm and arrived at Netley on April 24th, 1894. Previously to enlistment he had been a hard drinker, but he had never had syphilis. He arrived in India in October, 1892, and in the beginning of the following year he first complained of pains in the back and legs. There were no objective symptoms at that time, and he was supposed to be suffering from rheumatism; but in June of that year a small tumour was detected a little to the left of the umbilicus. This tumour gradually increased in size and in September it was said to be the "size of a cricket ball," with a feeble expansile pulsation, accompanied by a thrill and a slight systolic bruit. At this time the pain in the back had quite disappeared, but he suffered a good deal from pain in the abdomen in connexion with the tumour itself. He attributed his complaint to strains received while working with heavy guns. On arrival at Netley he was a healthy looking, well-nourished man. A tumour having all the characteristics of an aneurysm was situated about two inches below the left costal margin and about three inches to the left of the middle line as the man lay on his back. Through the abdominal walls it felt, with the hands placed on either side of it, about the size of a large orange and quite globular in shape. When the patient turned well over to the left side the tumour passed a little further into the left hypochondrium, and when he lay on the right side it passed over to about three inches to the right of the median line; it was, therefore, quite movable from side to side. Judging from its mobility, it was evident that the aneurysm was not on the aorta, and from its situation it was considered probable that it was either on a branch of the coeliac axis or on the superior mesenteric artery. A soft systolic bruit accompanied the expansile pulsation of the tumour, but there were no pressure symptoms; the pulsation of the femorals appeared to be normal. On admission to the Royal Victoria Hospital, Netley, in April, the man was not suffering from pain, though he complained of the discomfort and sleeplessness caused "by the beating of the tumour," but on June 22nd the abdominal pain recommenced and the tumour was noted as "steadily increasing in size." He had at first been admitted into the medical division of the hospital, and whilst there Tufnell's treatment by low diet, restriction in the quantity of fluids taken, exhibition of iodide of potassium, and absolute rest in bed had been tried. He had also been treated (at the suggestion of Professor Wright) with calcium chloride and the inhalation of carbonic acid, with the result of considerably increasing the coagulability of his blood, but with no effect on the size, pulsations, or solidity of the tumour. When medical treatment had failed, and the aneurysm commenced to increase in size, consultations were held on many occasions between the medical officers of both divisions of the hospital with regard to surgical treatment of the case, as to what method of surgical procedure was most advisable or least dangerous. It was decided that proximal pressure was not feasible on account of the situation of the tumour, and that distal pressure should not be attempted for the reason that it had never succeeded when tried in similar cases and on account of the probability of fatally injuring some of the abdominal contents. There, therefore, remained only the immediate treatment of the tumour itself by means of a laparotomy; and the methods rendered possible by this procedure were—(1) the ligation of the vessel leading to the aneurysm, and (2) the

introduction of wire or some similar foreign body into the sac in order to induce the formation of a clot. As regards ligation, the fact that the tumour passed over at least three inches to the right or left of the median line as the man lay on the corresponding side at least warranted a hope that it might be found to be so far forward on one of the branches of the abdominal aorta that sufficient of the healthy vessel might be found on the proximal side of it to enable a ligature to be applied at that situation; whilst, if this were found to be impracticable, then the treatment by wire could be carried out. The patient was an intelligent man; he knew he was suffering from a fatal disease, one, moreover, which could not be of long duration, and he expressed himself as being most anxious that something should be done for him in the way of operative treatment. He was willing that any procedure which offered even the faintest chance of cure should be undertaken; as he very forcibly put it—he "would prefer to die in hospital rather than go out to live for a short time on his friends." Under these circumstances he was transferred to the surgical division, and it was determined, on consultation, to perform laparotomy with a view to carrying out one of the methods above referred to.

On the night previous to the operation the skin surface was thoroughly washed with hot water and soap and afterwards with ether; it was then packed with lint dipped in a 1 in 40 carbolic lotion, which early next morning was changed for lint dipped in a 1 in 20 lotion. On July 23rd, at 10 A.M., chloroform having been administered, an incision was made in the median line from one inch and a half below the ensiform cartilage to within an inch of the umbilicus, but which was afterwards prolonged to the umbilicus. When all bleeding had been stopped the peritoneum was opened. The omentum was found to be firmly adherent to the abdominal walls over the tumour and to the tumour itself, and firm adhesions between the tumour and all the structures in its vicinity quite precluded any attempt being made to reach its base or pedicle; ligation of the vessel was, therefore, set aside as impossible. Preparations were accordingly made for the introduction of the trocar and cannula into the sac for the passage of steel wire. For this purpose it was necessary to make certain that no portion of the intestine overlay the aneurysm. The transverse colon and great omentum were pushed upwards off the tumour, and in doing so many adhesions had to be gently broken down; a very distended vessel came into view, and two small branches coming off from it were torn across and required ligation. Beyond this there was no serious hæmorrhage at this stage of the operation. When the colon and omentum had been pushed upwards off the tumour it still appeared to be covered by more than one layer of peritoneum; these were torn through by means of two pairs of dissecting forceps, and the tumour was laid bare over an area about the size of a shilling, showing a greyish-blue surface. At this point a very fine trocar and cannula were passed in at right angles to the long axis of the tumour for about two inches and a half, when the point appeared to be free within the sac. Hæmorrhage immediately occurred alongside the cannula, and continued very freely during the whole time the wire was being passed in (about five minutes). The wire was the finest steel wire, and it had been tightly coiled on a small reel so as to ensure its coiling up within the sac. It was passed through the cannula by means of a small pair of pliers, the wire being held by the pliers at about an inch from the end of the cannula, and in this way it was introduced inch by inch. Two yards were thus disposed of. When the outer end of the wire came flush with the end of the cannula it was pushed onwards and free into the sac by means of a knitting-needle, which had previously been filed down so as just to fit the cannula. The latter was then withdrawn, and in about a minute, under pressure on the orifice, the hæmorrhage above referred to ceased. No blood had entered the peritoneal cavity, so the latter was not flushed out. The wound was closed by two rows of sutures, one of chromicised gut for the peritoneum and deeper portions of the incision, and one of silver wire for the skin. I had intended to use also a continuous horsehair suture for the skin, but the others brought the surfaces so accurately together that this was unnecessary. Boracic acid powder was dusted over the wound, and an iodoform gauze and alembroth wool dressing was applied. The operation lasted an hour and a half; the patient took the anæsthetic well and recovered from it satisfactorily, shock being at that time

but slightly marked. No food or drink was given during the day, a few pieces of ice only being allowed. At 6 P.M. the temperature was 98.2° F. and the man seemed to be fairly strong and quite comfortable. At 7 P.M. severe hæmorrhage occurred, the dressings and sheet suddenly becoming saturated. The dressings were then removed and the blood was found to be coming from the lower end of the wound, which corresponded with the site of the trocar puncture. The wound was not reopened because I was certain that the hæmorrhage was not from vessels in the abdominal walls and because local treatment for hæmorrhage from the puncture in the sac did not appear feasible. Hæmorrhage again took place at 9 P.M., and also at 2.30 A.M. An ice-bag was then applied over the wound, a four-ply of iodoform gauze intervening, and no more hæmorrhage occurred. At 9 A.M. next day he was in a distinctly low condition, apparently suffering from shock from loss of blood, but not to any marked degree. He had vomited once or twice. The temperature was 99.6°, the pulse was weak (100), but quite perceptible at the wrist, and the respirations were 30 per minute and sometimes of a sighing character. He complained of extreme thirst. The wound was quite dry; the ice-bag was therefore removed and the dressings reapplied. He begged for lemonade, and some was allowed to be given him in small quantities. During the forenoon he vomited two or three times. He said he "wanted to cough, but could not." At 12 noon he was suffering from intense pain in the wound, and a hypodermic injection of morphine was given. At this time there was nothing in his condition to lead me to suppose that he was in any immediate danger of death. At 1 P.M. he was restless and inclined to retch. At 1.35 P.M. he died suddenly, the result, I have no doubt, of syncope, caused probably by his sitting up in bed, or attempting to do so, in order to vomit. He had lived twenty-seven hours after the operation.

At the post-mortem examination the stomach was found to contain an amount of fluid not warranted by the orders given regarding the quantity of drink to be supplied to him, and I have no doubt that the distended condition of the stomach tended to produce the syncope which caused the fatal issue. The aneurysm was found to be on the superior mesenteric artery. It had diminished very considerably in size after death in consequence of the cessation of tension in the sac. It was fusiform in shape, about six inches long, three inches and a half in diameter at the base, and somewhat less at the outer end. The dilatation commenced at the origin of the vessel and included the front wall of the aorta at this point. From the distal end of the sac the artery continued its course slightly dilated for an inch or so, but otherwise apparently healthy. The sac in its contracted condition was quite filled with firm recent clot entangled in the coils of wire, which were themselves entangled in each other, and its walls were lined with old laminated coagulum, this in parts being nearly half an inch in thickness. The adhesions of the tumour to the omentum had been broken down at the operation, but at the necropsy firm adhesions were found between its sides and the small intestines in its vicinity. There was no trace of blood in the abdominal cavity or any sign of commencing peritonitis. The sigmoid flexure and rectum were contracted to the size of the little finger, but they dilated to the normal diameter while being removed from the body, and no explanation of this condition was apparent. Both ventricles of the heart contained dark-coloured clots. The aorta in its whole length showed numerous patches of atheroma.

Mr. C. H. Moore of the Middlesex Hospital was the first surgeon to suggest the introduction of wire into the sacs of aneurysms not amenable to other methods of treatment. From a by no means exhaustive search through the literature of the subject I have collected records of ten cases of aneurysm treated in this way. Of these, two cases were cured, in two cases no definite result was produced, and in six cases death resulted. Mr. T. Holmes¹ has reported a case treated by Dr. Murray of Newcastle; the patient died from suppurative of the sac. Dr. Domville of Chatham² treated two cases with no definite result. Loreta³ introduced two metres of silver-plated copper wire into an abdominal aneurysm, and the patient recovered. Mr. Hulke⁴ introduced forty feet of steel wire into a thoracic aneurysm;

the patient died. Mr. Pearce Gould⁵ treated a thoracic aneurysm by means of thirty-two feet of steel wire; the patient died. Mr. Morse⁶ has reported a case in which he treated an aneurysm of the abdominal aorta by laparotomy and the introduction of one yard and a half of silver-plated copper wire, recovery taking place. Mr. H. Morris⁷ treated a case of abdominal aneurysm, but only one foot of wire could be passed; the patient died. Guido Baccelli of the Italian Paris Academy of Medicine recommended the use of watch springs for the purpose under consideration, and this was done twice unsuccessfully. The two cases above referred to as "cured" are probably the only ones in which this result has been achieved by this means. In considering the question of the propriety of performing this operation, I take it that the surgeon would only be justified in the procedure: (1) when his patient was in imminent danger of death from impending rupture of the sac of an aneurysm which was not open to treatment by other means offering a hope of cure; and (2) when the probable result of the treatment had been clearly explained to the patient, and he expressed himself as anxious that it should be undertaken. Both these conditions existed in the above case. The man's death, no doubt, was due in a secondary way to hæmorrhage. He died from syncope eleven hours after all bleeding had ceased and when he was apparently in a fair way to recover from its effects. A short time before his death his temperature was 99.6°, and his pulse was quite perceptible at the wrist. He was not, therefore, in a condition of collapse from loss of blood; but he was in a sufficiently low state to allow of the effort he made inducing a syncope from which the heart did not recover. As regards the hæmorrhage from the trocar puncture, I have no explanation to offer for its occurrence. The instrument was specially made for the case, and was extremely small, only large enough to pass the smallest steel wire made, and all bleeding from it quite ceased a few seconds after the cannula was withdrawn. In the accounts of other cases similarly treated hæmorrhage from the puncture is not mentioned as one of the dangers to be considered. The mechanical effect of the wire towards the formation of coagulum within the sac was found at the post-mortem examination to have been all that could have been desired so far; the sac was found filled with firm clot entangled in the coils of wire. But, after all, the question arises: Had the man lived long enough for the process of cure of the aneurysm to proceed so far as to block the vessel, what would have been the effect of this state of things on the nutrition and blood-supply of that portion of the intestinal tract supplied by the superior mesenteric artery?

The coloured illustration (painted by Surgeon-Colonel Irving) is an excellent representation of the aorta, the aneurysmal sac, and the wire and coagulum *in situ* soon after removal from the body; the specimen itself is in the museum of the Army Medical School, Netley.

Netley.

A CASE OF DOUBLE POPLITEAL ANEURYSM.

BY WALTER REID, M.D., L.R.C.S. EDIN.,
DEPUTY INSPECTOR-GENERAL, ROYAL NAVY.

A MAN thirty years of age was admitted into Haslar Hospital on Aug. 16th with an aneurysm in each popliteal space. The left one was a large sacculated aneurysm displaying the usual characters of that disease, whilst the right was considerably smaller and more elongated in form. There was nothing definite in the history of the case to account for the occurrence of these two aneurysms except that the man's general health was not good and that he thought he had strained himself whilst standing about on board a rolling ship at sea. Owing to my absence on leave at the date of the patient's admission to hospital, the case was taken in hand by Surgeon Townsend, who began to treat the left (or larger) of the two aneurysms by slow or intermittent pressure, leaving the other alone for the time being. By the application of Carte's tourniquet to the left femoral, according as it could be borne, consolidation gradually took place and at the

⁶ The Pacific Record for 1887.

⁷ THE LANCET, April 16th, 1887.

end of five weeks was completed and the aneurysm cured, a large, hard, non-pulsating mass remaining in the popliteal space. Having now returned to duty I determined to undertake the treatment of the right aneurysm by the method with which my own name is associated in surgical writings, and which consists in locking up the blood in the aneurysmal cavity by means of elastic appliances sufficiently long for its coagulation *en masse*, and not by the deposition of fibrinated laminæ as usually follows treatment by ligature or slow pressure. I began by keeping the patient at rest for a few days on a light non-stimulating diet. Iodide of potassium was also administered with the view of increasing the plasticity of the blood. Carte's tourniquet was occasionally applied to the femoral for the purpose of opening up the collateral circulation preparatory to the occlusion of the vessel by the rapid consolidation of the aneurysm. On Oct. 3rd, the patient consenting to take chloroform if necessary, I carried out the method originally described by myself,¹ using in addition a protector over the aneurysm so as to take the pressure of the elastic bandage. This was made of gutta-percha so as to cover the tumour in the popliteal space with the joint somewhat flexed, and sufficiently strong to protect it effectually from direct pressure. I now applied an elastic bandage firmly and evenly from the toes upwards and over the protected aneurysm to the level of the middle third of the thigh. Here a soft elastic constrictor was secured over several turns of a flannel bandage. The elastic bandage and protector were now removed, whilst the constrictor was kept in position. The blood was thus locked up in the aneurysmal cavity, whilst the rest of the limb below the constrictor remained bloodless. It is important to render the limb bloodless in this way, as otherwise congloba might form in the veins and smaller arteries during the arrest of the circulation by the constrictor. Were they to do so there might be a risk of their interfering seriously with the circulation through the limb after the main vessel has become obstructed by the rapid consolidation of the aneurysm, and the blood-supply has to be passed down by the collateral branches with diminished force. The patient was now covered with warm blankets, the limb being semi-flexed and the elastic constrictor remaining in position. He complained of no pain during the first forty-five minutes; after this he began to feel much distressed, but preferred to do without chloroform. At the end of an hour—the aneurysm being then hard, solid, and decidedly smaller—I carefully adjusted a Carte's tourniquet upon the femoral, and removed the constrictor and flannel bandage; but about five hours afterwards on easing off the tourniquet a pulsation (faint, tremulous, and at times hardly perceptible) was felt in the aneurysm. This symptom occurring at this stage has been noted in other cases treated by the same method, and was referred to by Mr. Pearce Gould in an interesting paper read by him at the International Medical Congress in 1881, when this mode of treating aneurysm was discussed. Mr. Pearce Gould explains its occurrence by the clot contracting more rapidly than the sac upon it, thus leaving a space between the two, which after a time becomes filled either by the deposition of fibrin or by further contraction of the sac. In the present case it ceased after five days, and the vessel became occluded in the lower part of Hunter's canal. It is instructive at the date in which I write to observe the conditions arising from the treatment of these two aneurysms in the same patient by methods differing essentially from each other in principle. In the left one, treated by slow and intermittent pressure, which aims at consolidation by the gradual deposition of fibrinated laminæ in the cavity of the aneurysm, the remains now form a hard, unyielding lump in the popliteal space, causing a good deal of discomfort to the patient and interference with the use of the limb. It must be some time before this mass of fibrin can be absorbed to any extent and cease to trouble the patient. On the other hand, in the right aneurysm, treated by a plan which aims at the rapid formation of an ordinary blood-clot in the aneurysmal cavity, the soft material has contracted as well as the sac which encloses it, so that there is only a small mass left in the floor of the popliteal space, which can hardly be distinguished by the observer and is not felt by the patient in any way. Another point of difference in the results is that in the left limb, treated by the slow method, no pulsation can be felt in the femoral

artery below the origin of its deep branch in the groin, whilst in the right limb the femoral can be felt pulsating in the lower part of Hunter's canal. In my original case, in which the patient died eight months after cure from other causes, I had an opportunity of examining and making a preparation of the parts. This preparation is now in Haslar Museum and shows that the vessel is only occluded for about two and a half inches of its course.² It would appear, then, from these two cases that when this plan of treating popliteal aneurysm is successful the circulation is brought down through the main vessel of the limb and becomes finally arrested only a short distance from the aneurysm, as if, in fact, the latter were cut out and the vessel tied.

Haslar.

THE CONDITION OF THE BLOOD IN THE CYANOSIS OF CONGENITAL HEART DISEASE.¹

By G. A. GIBSON, M.D., D.Sc. EDIN.,

PHYSICIAN [TO THE DEACONESS HOSPITAL; ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY; LECTURER ON MEDICINE AT MINTO HOUSE, EDINBURGH.]

NOTWITHSTANDING the numerous works published within recent years on the state of the blood in disease, we nevertheless not only need information as to the changes which it undergoes in a great variety of different conditions, but we also require explanations to account for many of the alterations which are generally recognised. This is the case even in regard to some of the affections met with in every-day practice; in the disturbances of the circulation produced by valvular diseases, for example, there are some modifications of the blood of common occurrence, but as yet insufficiently known and inadequately explained. More particularly is this true of the state of the blood in the cyanosis of congenital heart disease, which presents changes which have from time to time been recorded, but have not yet received satisfactory elucidation. A most interesting case of congenital disease of the heart has lately been for some time under my observation, and from the clinical features presented by the patient some conclusions have been forced upon me to which attention will in this paper be briefly directed.

A boy aged eight years was admitted to the Deaconess Hospital on Oct. 25th, 1894, complaining of breathlessness on exertion. Both parents were alive and had always been healthy; he was one of a family of eleven, of whose members two sons had died, one from scarlet fever and another from hydrocephalus, but the remaining six sons and two daughters were in good health. At the time of his birth the patient was apparently a healthy infant, but when a few months old he became bluish in colour and had always since been delicate. He had an attack of scarlet fever some years ago from which he recovered perfectly. On admission he was observed to be deeply cyanosed; the skin everywhere was of a bluish tint, the lips were almost black, and the conjunctivæ were dusky. The fingers and toes were markedly clubbed, and the nails, which were much curved, were almost black. The patient was 3ft. 9in. in height, and weighed 2st. 10lb. The temperature was below normal, but has fluctuated between 97° and 99° F. The alimentary system showed no symptoms of disturbance. The second dentition was in progress. The tongue was clean, but of a very dark purple colour. The liver exactly reached the costal margin in the right mammillary line. The hæmopoietic system presented some interesting facts. The spleen reached to the mid-axillary line, and was therefore of the usual size. On examination of the blood with the hæmoglobinometer the hæmoglobin was found to be 110 per cent. With the Thoma-Zeiss hæmocytometer the red corpuscles were seen to be 8,470,000 per cubic millimetre, while the white corpuscles numbered 12,000. The spectroscopic showed the characteristic double band of oxyhæmoglobin. With regard to the circulatory system, the patient on any exertion became much more cyanosed and panted violently, but when lying quietly in bed showed much less cyanosis and almost no breathlessness. On inspection there was no visible pulsation in the neck, and in the precordial region there was no impulse save the apex

¹ THE LANCET, Sept. 25th, 1875.

² THE LANCET, Aug. 5th, 1876.

¹ Read before the Edinburgh Pathological Club on Dec. 19th, 1894.

beat in the fifth left intercostal space. The pulse varied from 64 to 114. The vessel was rather empty, the pressure low, and the pulsation regular. No thrill was felt in the precordia, but an impulse with both systole and diastole, and the apex-beat was determined to be one inch and three-quarters from the mid-sternum. On percussion the borders of the cardiac dulness were found at the level of the fourth costal cartilages to be one inch and a half to the right and two inches and a half to the left of the mid-sternal line. A loud rasping murmur was heard over the entire precordia; its maximum intensity was at the left edge of the sternum at the level of the fourth costal cartilage, and it was propagated upwards as far as the external ends of both clavicles—to the right as far as the mammilla, to the left four inches beyond the mammilla and downwards along each costal margin to the same extent—viz., two inches and a half below the level of the xiphoid cartilage. No murmur could be heard in any vessel. The thorax was distinctly pigeon-breasted. There were numerous rhonchi throughout the chest, but otherwise the respiratory system presented no symptoms requiring notice. The respirations numbered 24 per minute. The urine was pale in colour and acid in reaction; its specific gravity was 1022. It contained no abnormal constituents. The integumentary system was, apart from the high degree of cyanosis, not distinguished by any special characters, and the nervous system was in all respects normal. Although the patient had never been taught, on account of his state of health, he was an intelligent and observant boy, always enjoying high spirits.

The diagnosis of the cardiac lesion was attended by some difficulty. There could be no doubt that the condition was congenital, for although the cyanosis only showed itself after the lapse of some months from the date of birth, the patient had not during the interval suffered from any acute disease capable of causing endocarditis. In this respect the history of the case is in accord with that of most congenital heart lesions. The maximum intensity of the murmur being almost in the tricuspid area might favour the view that there was regurgitation at the right auriculo-ventricular orifice; but such an explanation is negatived by the absence of any venous symptoms in the neck. On the other hand, the murmur might be produced by obstruction at the pulmonary orifice, and heard with greatest intensity over a dilated and hypertrophied right ventricle, such as undeniably is present in the case; or, again, the murmur might be the result of a communication between the two ventricles, caused by a perforate septum ventriculorum, allowing a stream of blood to flow from the left cavity into the right, and thus to produce over the right ventricle a systolic murmur. The lesions probably present, judging not only from the clinical facts of this case, but also from the experience of similar cases, are some obstruction at the pulmonary orifice and an imperfect ventricular septum. Such is the provisional diagnosis of the case.

Attention must now be given to the condition of the blood. As has been stated in the brief abstract of the case, the amount of hæmoglobin was 110 per cent., and the number of the hæmocytes and leucocytes respectively 8,470,000 and 12,000 per cubic millimetre. In another patient, a boy aged two years and four months, suffering from congenital heart disease (for the opportunity of observing whom my thanks are due to Dr. John Thomson), the hæmoglobin was 92 per cent., the red corpuscles numbered 6,700,000 and the white corpuscles 12,000 per c.mm. The number of the blood corpuscles in congenital diseases of the heart appears to have been first observed by Toennessen, who found in a girl aged ten years, with congenital pulmonary stenosis, 7,540,000 hæmocytes, and in a boy aged thirteen years, suffering from the same affection, 8,820,000 per c.mm. Since his observations similar facts have from time to time been placed on record. Carmichael, for example, in publishing a most interesting case of congenital heart disease recently, states that the patient had 8,100,000 red corpuscles and 16,000 white corpuscles per c.mm.

Now, before entering upon the question as to how such an increase can be produced, it may be well to recall the two diverse explanations of cyanosis—the one, that of venous stasis, originating with Morgagni; the other, that of a mixture of the arterial and the venous blood, suggested by Hunter. Both theories have been supported by numerous observers from the time of their inception until the present day, but the preponderance of opinion is in favour of the theory of Morgagni. The view of Hunter may be said to be negatived by the simple facts that in many cases permitting the mixture of arterial and venous blood

there is no cyanosis, and that in many cases of cyanosis there is no possibility of the mingling of venous and arterial blood. Starting with the conception that cyanosis is produced by obstruction to the circulation and venous stasis, the question now arises why this condition should be associated with an increase in the number of the blood-corpuscles. It is not only in the cyanosis of congenital lesions that the increase is found, but in all cases where cyanosis is really present on account of failure of the circulation. To this point Toennessen and Schneider have particularly called attention, and of the accuracy of the observation anyone can convince himself by investigation of the blood. The work of Malassez seems to show that the blood in the superficial parts of the body contains a larger number of red corpuscles than that from the deeper layers, and Perzoldt and Toennessen believe that this increase is caused by the loss of fluid from the surface, while the blood of the interior is constantly receiving fluid from the alimentary canal. Even if this be correct, it cannot be accepted as an explanation of the great increase in the number of the corpuscles found in cyanosis, as it would involve the postulate that in some cases where the number of corpuscles is nearly doubled, the quantity of the fluids of the blood must be reduced nearly to one-half. Cohnheim's celebrated experiment of tying the crural vein of the frog, which is followed by a considerable increase of the corpuscles in the vessels, with the transudation of serum into the surrounding tissues, may be regarded as an explanation of the moderate increase in the cases accompanied by anasarca, but it has no special bearing upon cases of congenital cyanosis in which there is no drain of fluid into the tissues. It may possibly be held that in such cases the lymph vessels are unusually active, and that the fluid constituents of the blood are as rapidly absorbed as they transude. Such an opinion can scarcely be seriously entertained. The backward pressure on the venous system which causes the transudation must tell on both terminations of the absorbents. It may be admitted freely that the increased pressure on the peripheral veins may tend to raise that impelling the fluids into the commencement of the lymphatics, but it must not be forgotten that an elevation of pressure in the great veins will hinder the return of the lymph by pressing upon the openings of the lymph vessels into the veins. It is probable that the increase in the red corpuscles may be to some extent compensatory in cases of cyanosis. To say this, however, is not enough; it affords no rational explanation of the process by which the increase is brought about. Nature does not work by such direct methods as would require to be invoked if the increase of the corpuscles were regarded as a simple compensatory change, balancing the diminished power of oxygenation. Compensation in valvular lesions, for example, is produced by the definite structural changes constituting hypertrophy, caused by increase of work, and compensation in cyanosis must have some reasonable explanation also. It seems to me that such an explanation may be found in a consideration of the functions of the red corpuscles under changed conditions. In venous stasis the corpuscles are insufficiently oxygenated, they cannot perform such an active part as oxygen carriers, and they cannot yield so much oxygen to the tissues. It must further be remembered that in cyanosis there is less metabolism in the tissues, and therefore less waste produced. In a word, the functions of the corpuscles being lessened, the tear and wear which they undergo is reduced, and the duration of their individual existence increased. The number of the corpuscles must in this way be proportionately augmented, and this must lead to the numerical increase, as well as to the high percentage of hæmoglobin, until a balance is struck between the production and the destruction of the blood-corpuscles.

It is a pleasure to express my warm thanks to Dr. J. G. Cattanach, resident medical officer to the Deaconness Hospital, for his unwearied assistance in the investigation of the blood in the cases to which reference has been made and in the examination of their clinical details.

THE RELATION OF BACTERIA AND THEIR TOXINES.¹

By E. KLEIN, M.D., F.R.S.,

LECTURER ON GENERAL ANATOMY AND PHYSIOLOGY IN
ST. BARTHOLOMEW'S HOSPITAL.

THE subject to which I would particularly draw your attention this evening is the nature of the activities of pathogenic bacteria. For convenience I shall formulate two propositions, adducing facts in support of each, and then I shall go on to discuss certain considerations having to do with this subject matter.

PROPOSITION 1: *Pathogenic bacteria produce by their growth and multiplication specific poisonous substances which we call toxins.*—These poisons differ one from another according to the species of pathogenic bacteria, and the changes induced in the animal body by different microbes are due to these toxins. Before the existence and nature of these substances were recognised it was held—as, for instance, in the case of anthrax—that the induced illness was due to mechanical action exerted by the bacillus on the body of the affected animal. As the anthrax bacillus is an organism which grows freely, and perhaps more conspicuously, in the presence of oxygen, it was thought that this bacillus consumed all the oxygen in the tissues of the infected animal and in this way deprived it of life. It was soon discovered, however, that this was not a sufficient explanation, for it was found that an animal could be made fatally ill with anthrax and yet antecedent to its death by the disease the bacilli of anthrax could only in small numbers be detected in its blood. Hankin was the first to demonstrate that it is possible to procure by artificial culture of microbes in nutrient media certain toxic substances comparable to toxic albumoses. Fraenkel afforded a like demonstration, and Sidney Martin elucidated the subject to a much larger extent; but before toxins were isolated by their methods evidence existed tending to show that certain bacteria produced toxins. Thus, the microbes of typhoid fever and septicæmia were known, when grown in an albumen mixture, to contribute to such medium a poisonous quality. Roux and Yersin were, however, the first to demonstrate that the broth in which the diphtheria bacillus had been cultivated contained poison in a very concentrated form. A whole series of researches were next made by Kitasato and Brieger on the tetanus bacillus, with the result of demonstrating that injection into the animal body of the pure tetanus toxins obtained in artificial culture produced symptoms identical with those induced if the tetanus bacteria themselves were introduced into the experimental animal and allowed to grow and multiply therein. There can, therefore, be no question whatever as to the proposition that the pathogenic bacteria produce in the animal body toxic substances.

PROPOSITION 2: *Toxins as far as they have been investigated are definite chemical bodies.*—As a result of chemical analysis by Dr. Sidney Martin, it has been found that albumoses and alkaloids are present in the animal body in anthrax; and that in diphtheria there is present in the false membrane a body which behaves in every respect like a ferment, which ferment in turn acting on the tissues produces acid and alkaloidal bodies and albumoses. Similarly it has been found that, in artificial media, the bacilli of diphtheria and tetanus elaborate each a ferment, whereas under like conditions the bacilli of anthrax elaborate albumoses and an alkaloid. What then, it may be asked, is a given toxin? Is it the secretion of a bacterium, like the ferment of diphtheria, for instance; or is it of the nature of a proteid body liberated by metabolism in the medium in which the bacterium has grown; or, again, is it part and parcel of the bacterial body itself? The poisonous substances produced in the animal body by the life processes of bacteria must be carefully distinguished from the poisonous substance or substances present within the protoplasm of the bacteria themselves. All observations tend to show that there is a definite distinction to be drawn between the poisons which may be present in the bacteria themselves and the poisonous substances liberated or elaborated by these organisms. When certain bacteria are introduced in large quantities into the peritoneal cavity of a

rodent these bacteria themselves without any of their metabolic products are capable of producing symptoms of poisoning. For instance, if the growth of a given microbe scraped from the surface of a solid culture medium be distributed in some neutral fluid and then injected into an animal it is the bodies of the bacteria themselves that are introduced thereto, not the toxins, which they have elaborated in the culture medium. And it has been found, as a matter of experiment, that such inoculations produce, in the case of several species of bacteria, a poisonous action quickly causing fatal peritonitis; in two or three hours the animal is ill, and within twenty-four hours the illness is fatal. The typhoid bacillus and several other microbes behave in this way. It matters not whether the bacteria are introduced alive or dead into the peritoneal cavity. If the bacteria are previously killed by exposure to a temperature of 70° C. their bodies produce the same poisonous action, though it must be added that the poisonous action is more pronounced if smaller quantities of the living bodies are used than when larger quantities of the dead bacteria are employed. Evidently when the living bacteria are introduced in small quantities they go on growing and produce their toxins. The bacteria *per se* are in some cases, but not in all, poisonous. Thus, if the anthrax bacillus, or the diphtheria bacillus, or the fowl cholera bacillus, is introduced into the peritoneum of rodents no poisonous action results. The protoplasms of these microbes are not, like the protoplasm of the typhoid bacillus or of the vibrio of cholera, poisonous. Furthermore, as regards microbes whose protoplasms are poisonous, if a non-fatal dose—sufficient to make an animal ill, but not to kill it—is injected into the peritoneal cavity such an animal is protected from further protoplasmic poisoning by the same bacterium; but it is not protected against the toxins elaborated by the same species outside the animal body in artificial media. A very curious observation has been made with reference to these bacterial bodies. They probably contain more than one kind of poison. If, for instance, the enteric bacteria are killed by heat, and the precipitate extracted from their bodies by water, it is possible to wash out a substance which produces a febrile rise of temperature in experimental animals, and substances such as this are called “pyrotoxins” because they are capable of producing fever. These, however, are not the substances which have a permanent protective action when bacteria alone are introduced into an animal; it is some other kind of substance bound up in the protoplasm of the microbe that protects the animal against further inoculation with the bacterium *per se*.

And next as to antitoxins. When an animal has passed through one attack of a given infectious disease—that is, when an animal has served as a host for the growth and multiplication of a particular pathogenic bacterium—it is found that its blood has acquired a peculiar faculty. The blood has become capable, not only of inhibiting further growth of the bacterium, but also of neutralising the toxins produced by the bacterium. Thus, if the cholera vibrio is introduced into the peritoneal cavity of a rodent in quantity just sufficient to produce an illness that does not prove fatal, such rodent ultimately withstands repeated injections of otherwise fatal doses of the vibrio. And further, if now blood of the animal that has thus acquired immunity is taken from it and introduced into the peritoneal cavity of another rodent this second animal will not become ill at all; it is protected. This has been shown in the case of tetanus, diphtheria, and so on. Animals, therefore, which have acquired immunity possess in their blood a something that they had not before, and this something belongs to a group of substances called “antitoxins.” These antitoxins must be very complex bodies because they are capable, not only of inhibiting the life processes of bacteria, but also of neutralising the toxins previously elaborated and that have been dissociated from the bacteria which produced them, and these two functions are, be it observed, utterly different.

How are these complex antitoxin bodies thus possessing dual functions produced? There is a variety of theories as to this. In the first place there is the theory that these antitoxins are produced by the tissues themselves as a sort of defence against the toxins which have gained access to them, the toxins being thought of as stimulating the tissues to the production of certain defensive substances which are therefore called “antitoxins.” In diphtheria the antitoxins produced in this way by the cells of the tissues are considered to comport themselves just like ferments. This is the theory held by the French school. The Munich school says: There is no reason why the toxins themselves should

¹ Abstract of a paper read before the Epidemiological Society on Dec. 14th, 1894.

not become converted into antitoxins. There is, however, little evidence in support of this view; and, indeed, there is some evidence which militates against it. Moreover, it seems to be reasonable to assume that the toxins stimulate the animal body to the production of antitoxin. There is yet another theory, and that is that possibly the bacteria indirectly play a part in the production of these defensive antitoxins. This raises the question, What becomes of the bacteria themselves in the animal that has been made ill by them and has recovered? The theory that bacteria have been in such cases swallowed up by phagocytes is long since dead and buried. It is now perfectly well established that acquired immunity is purely of a chemical nature, and therefore the theory of phagocytes is superfluous. But the bacteria may nevertheless themselves yield some substance which may assist in the production of these antitoxins. For when an animal is recovering from an infectious disease the bacteria which caused it degenerate *pari passu* with the progress of recovery, and their substances become absorbed and pass into the general tissues of the animal, so that the bacterial bodies themselves become part of its tissue juices. In some cases there is an excretion of bacteria, but not very generally; in most cases they are absorbed in the way I have noted. That incorporation of the dead bacteria with the tissues of the recovered animal may have to do with its own immunity and with the antitoxic quality of blood serum withdrawn from it is suggested by the following facts. When dead bacteria are introduced into the peritoneal cavity of a guinea-pig they are capable of protecting that animal's peritoneum against the growth and multiplication there of the living bacteria subsequently introduced. This is the case with the cholera vibrios, the typhoid bacillus, and the colon bacillus. Indeed, it is not very difficult to imagine that other substances superadded to the tissues—as, for instance, dead bacterial protoplasm—may form part of these antitoxins, and I, for my part, incline to this view. In a word, I suspect that antitoxic serum obtains from dead bacterial protoplasm that it has assimilated its power of inhibiting the processes of living bacteria, and that its power of neutralising the already formed metabolic products of bacteria is due to tissue change resulting from contact of the tissues themselves with metabolic poison. But, whatever the nature of these antitoxins, it will no doubt be found that they are not of the simple character that has been assumed—namely, merely secretions of tissue juices—they must needs be of a very much more complex nature.

A CASE OF POST-MORTEM PARTURITION.

By ALBERT GREEN, M.B., L.R.C.P. LOND., M.R.C.S.,
SURGEON TO THE CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.

THE following are the particulars in reference to the post-mortem parturition mentioned in an annotation in THE LANCET of Nov. 24th, 1894.

A single woman aged about twenty, and following the occupation of dressmaker, lived with her father and mother in a model dwelling-house in Chesterfield of which the father had the management. For about a week previous to Wednesday, Oct. 24th, she had had headache, but otherwise was quite well. The headache does not appear to have been severe and she took but little notice of it. On the morning of the 24th she had breakfast with the other members of the family and appeared as well as usual. In the middle of the day she was not down to dinner, but remained upstairs complaining of headache. In the evening, about 10 o'clock, her father went to the bedroom and found her in bed; she was still complaining of headache. She told him he might go to bed as "she should be all right in the morning." Later (about 11 P.M.) a friend went up to see her. Except for the headache there seemed to be nothing much the matter with her. She laughed and talked as usual. The friend left some time between 12 midnight and 1 A.M. Between 1 A.M. and 2 A.M. the sister was called to her room. She found her out of bed, sitting on the floor with her back against the wall. She did not speak and appeared unconscious. With assistance she was lifted on to the bed. The witnesses speak of her at times becoming "stiff," of her eyes being fixed, of her legs (though "stiff") trembling, and of the arms and eyelids "working." The father was called and went for a medical man. He

arrived in about half an hour and from the symptoms then observed he expressed an opinion that some alkaloidal poison had been taken. He examined the abdomen and was satisfied that the woman was pregnant and near full time. The "fits" are stated to have each lasted about ten minutes; the tonic nature of the convulsions seems to have been more marked than the clonic. There seems to have been very little struggling. I thought that the long duration of each "fit" might be accounted for by its being made up of a series of "fits." She never regained consciousness till the time of her death, which was between nine and ten in the morning. The "fits" are said to have become less frequent towards the end. At the commencement they are stated to have occurred at the rate of about three or four in an hour. When the medical man (Mr. Bowker) arrived he found that she had bitten her tongue, and a piece of cork was placed between the teeth. Mr. Bowker again visited her about 9 A.M. He found her in a comatose condition and dying. The pupils are said to have been dilated from the first, and the face to have been very pale during the "fits." Until the medical examination none of her family had the slightest idea that she was pregnant. Her figure was short and broad, and she was very corpulent. So much for the symptoms during life.

The inquest, which was held on Friday, Oct. 26th, was adjourned till Tuesday, Oct. 30th, in order that a post-mortem examination might be made and the contents of the stomach, with the other viscera, analysed. By order of the coroner I made the post-mortem examination on Saturday afternoon, Oct. 27th, about fifty-three hours after death. The body had been laid out in the usual way by two women on Thursday morning, about two hours after death. The body was lying on its back on a small bed and was covered with a sheet. The legs were tied together at the ankles. On lifting the sheet I saw a fleshy body lying between the thighs of the mother. This was the back of a full-time or nearly full-time child. The legs were extended at the knees and flexed at the hips, so as to be doubled up underneath the child's body with the feet near its chin. The head, face downwards, was also flexed on the chest. The head was next to the vulva, so evidently it had been a breech presentation. The fundus of the inverted uterus protruded from the vulva, and still attached to this was the placenta. The umbilical cord was much shorter than usual. On separating the placenta and attempting to push back the fundus into position I found that the intra-abdominal pressure immediately forced it back again. The perineum was ruptured to a considerable extent. I was unable to decide by the naked-eye appearances of the laceration as to whether this had been done during life or after death. There were no marks of bleeding on the linen on which the body rested or on the shirt which partly covered it. The edges of the laceration were gaping and the opposing surfaces had a reddish appearance, dotted with yellowish specks. I may here say that the evidence of the women who laid her out proved conclusively that there was no birth, and no signs even of an impending birth, at the time they performed those duties. The vulva was then free from injury of any sort, and so far as they could judge was normal in appearance. Considering the time that had elapsed since death (only fifty-three hours), putrefactive changes were very marked. The face was greatly swollen and quite black. The features were unrecognisable. The front of the chest was covered with large dark-green patches, especially marked about the breasts. The surface of the abdomen was similarly affected, but to a less extent. The abdomen itself was enormously swollen, and on cutting into it gas escaped with great force. The body had been kept since death in a fairly cool room, though the weather for the time of year was warm and damp. The body was very fat. The stomach contained only a few drachms of thick, yellowish fluid. There were many little air vesicles scattered over its mucous membrane, and reddish patches, probably due to post-mortem staining. The liver was so soft as to be almost diffident. There was nothing noticeable about the condition of the kidneys or the brain. The bladder was empty. The stomach and contents, with the duodenum, the liver, kidneys, and spleen, were sent to Mr. Allen of Sheffield for analysis. He satisfied himself as to the absence of any strychnia, but in consequence of the advanced state of putrefaction of the viscera, he stated it would have been a matter of considerable difficulty and would have required a much longer time than had been given him to have searched for the various other alkaloidal poisons. The symptoms during life appeared to point to strychnia as the only one likely. He

was surprised at the number of cadaveric alkaloids that had already been formed, and remarked upon the definite reactions which they gave out in the process of testing.

In conclusion, the interesting features of this case are—(1) the difficulty in the diagnosis of the symptoms during life; (2) the post-mortem birth of the child due probably to post-mortem contraction of the uterus, or to pressure of gases generated by putrefaction in the abdomen, or to both those causes together—no doubt labour had commenced previously to death; (3) the well-marked laceration of the perineum; (4) the inversion of the uterus; and (5) the remarkably rapid putrefactive changes that had occurred. The fact of its having been a breech presentation seems to make this case even more remarkable. In giving evidence at the inquest I expressed an opinion—(1) that the symptoms observed during life did not correspond exactly with those of any known poison; (2) that puerperal convulsions would be sufficient to account for death and probably caused it; and (3) that it was possible for the child to have been expelled from the maternal passages after death if labour had commenced previously. A verdict was returned in accordance with the medical evidence.

Chesterfield.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

MALIGNANT JAUNDICE IN A CHILD TWO YEARS OF AGE.

By H. B. DONKIN, M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN.

SUCH a case as the following, which has recently occurred in my hospital practice, is sufficiently rare to be worthy of record in the columns of THE LANCET.

A girl two years of age was admitted into the East London Hospital for Children on Nov. 22nd, 1894, with well-marked jaundice of skin and conjunctivæ. She was said to have been always weakly and to have had pneumonia a year previously, but no other definite illness. Her family history was good. Her illness began three weeks before admission with a "cold." The child had a cough and was constipated and sleepy; the appetite failed, but there was no coryza. Jaundice was noticed two weeks before admission; the motions were white and the urine was of deep colour, staining linen. She vomited four days before admission and was restless at night, throwing herself about. On admission jaundice was found to be well marked, and the child appeared to be very ill and rather restless. The lips were of good colour. There was no cough and the temperature was normal. Nothing abnormal was revealed by physical examination of the heart and lungs. The liver was felt one finger's breadth below the costal margin, somewhat hard and smooth. The upper limit of dullness was perhaps a little lowered. No other abnormality could be detected anywhere. She passed a fairly quiet night on the 22nd, though she was somewhat restless. About ten o'clock on the morning of the 23rd she became very restless, and soon after grew apparently unconscious of her surroundings. Delirium set in, soon developing a maniacal character, the child throwing herself about in bed and biting her clothes and hands or anything she could reach with her mouth. The pupils were equal and rather contracted, but reacted to light. The pulse was 120, irregular; the temperature was still normal. The urine and fæces were passed unconsciously. The jaundice had increased in intensity. The child was very thirsty. Petechiæ now appeared on the front of the legs. The child cried very little, but moaned when disturbed; the tongue was covered with a dirty white fur. The patient remained maniacal all day, but during the evening became quieter and drowsy; the pupils were dilated and sluggish at 10 P.M.; the temperature was 100° F.; the pulse was 140 regular. During the night coma gradually set in, the petechiæ became more numerous, and the jaundice more intense. About 5 A.M. on the 24th the child vomited a quantity of blood and died shortly afterwards.

Although a post-mortem examination could not be obtained in this case, and there was no opportunity of examining the

urine for leucin and tyrosin, the diagnosis of malignant jaundice or "acute yellow atrophy" seems amply justified. The case was in all respects clinically similar to two others I have seen in children aged two years and a half and six years respectively, where post-mortem examination proved complete destruction of the cellular liver structure. These cases I have reported elsewhere in some detail. In none of these cases was there evidence during life of any considerable diminution of the liver, and in at least one of those examined after death the liver was not below the average in weight. A practical lesson to be learnt from such cases is to be very guarded in the prognosis of all so-called and apparent cases of "simple" or "congestive" or "catarrhal" jaundice in children when the jaundice does not abate within a week, and still more when it increases.

Harley-street, W.

ABNORMALITY OF THE CHORDA TYMPANI.

By RICHARD LAKE, F.R.C.S. ENG., L.R.C.P. LOND.,
PATHOLOGIST AND REGISTRAR TO THE THROAT HOSPITAL,
GOLDEN-SQUARE, W.

FOR the chorda tympani to take an irregular course in its passage across the membrana tympani must be exceedingly rare, so I send drawings of the external and internal surfaces of the left membrane where the following abnormality occurred. The chorda made its exit at the usual level, but

FIG. 1.

FIG. 2.

External surface.

Internal surface.

1. Chorda tympani. 2. Insertion of tensor tympani.

instead of arching upwards it ran almost horizontally forwards to about the junction of the lowest fourth of the handle of the malleus with the remainder; it was clearly visible through the membrane from the meatus. On the inner side, after reaching the malleus, it runs upwards, passing off to leave the tympanus by the canal of Huguier, keeping below the tendon of the tensor tympani. I am inclined to think Fig. 5, Plate xi., in the "Atlas of Diseases of the Membrana Tympani" is a variation of this state of things.

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

MIDDLESEX HOSPITAL.

TWO CASES OF OPERATION FOR CYSTIC BRONCHOCELE; REMARKS.

(Under the care of Mr. HENRY MORRIS.)

THESE cases form a contribution of interest to the surgical treatment of cysts of the thyroid gland. The method of excision, or enucleation, is the one which surgeons usually prefer at the present time, and it yields very good results. We published a series of cases last year in the *Mirror of Hospital Practice* which had been under the care of Mr. C. J. Symonds and in which this method was employed with considerable success. The first of the two cases which follow shows how much may be done by enucleation. The multiple cysts were easily removed and nothing but healthy tissue was left.

CASE 1. Multiple adenomata of the thyroid gland (cystic bronchocele); removal of seventeen cysts from the thyroid gland. (For the notes of the case we are indebted to Mr. E. Griffin, the dresser.)—A young woman twenty-one years of age was sent to Mr. Henry Morris by Mr. Daglish of New Romney, Kent, suffering from a very unusual form of bronchocele. She was admitted into Helena Ward of the Middlesex Hospital on March 16th, 1894. She had enjoyed good health and her family history was good except that a sister was beginning to develop a bronchocele. The enlargement commenced about seven years ago, and was treated by the external application of iodine, but without effect, as the swelling continued to increase and her voice became weak. Between four and five years ago her neck became painful, and since then she had been subject to constant headache. She had never had any difficulty in swallowing or breathing; occasionally throbbing had been felt for two or three days continuously, and at these times she said the enlargement had increased and had been more painful. The patient, a short, thickset brunette with a waxen oedematous face much resembling myxœdema, had on admission a symmetrical enlargement in front of the neck having the general outline of the thyroid gland. There were no other signs beside the facial aspect at all suggestive of the myxœdematous state. The isthmus of the thyroid extended upwards above the lower border of the thyroid cartilage. The lateral lobes reached from the upper border of the thyroid cartilage downwards as low as the clavicle, and out-

FIG. 1.

Shows the relative sizes of eleven of the tumours removed.

wards beneath the sterno-mastoid muscles. In the isthmus, slightly to the right of the median line, there was a very hard movable tumour the size of a horse bean; it was painful and tender, and had attached to it by what felt like a cord a second somewhat smaller tumour. A third circumscribed mass connected with the isthmus, separated from the general enlargement, and situated above and behind the left sterno-clavicular joint, could be made out. It was about the size of a walnut, but was less movable and less free than the other two tumours of the isthmus. The enlarged lateral lobes had not a uniform consistence, but for the most part felt soft and were without fluctuation or thrill. The patient suffered much discomfort from the bronchocele, especially when lying down. Her most comfortable position was on her right side, with her head well turned towards the right. On laryngoscopic examination Mr. Leopold Hudson found both vocal cords in all respects normal except that the left was a little more sluggish in its movements than the right. This was probably caused by chronic inflammation of the mucous membrane covering the left arytenoid cartilage, an extension from chronic pharyngitis, of which traces still existed. The weakness of voice was probably due to the failure of the left vocal cord to approximate accurately to the right cord. On March 30th, the patient being anaesthetised, an incision was made near the middle line parallel with the border of the right sterno-mastoid; the skin was then reflected sufficiently to expose the right lobe

and isthmus, and the tumours above described were removed. During the dissection several other tumours of varying sizes were detected in the right lobe and the isthmus, and were enucleated from amidst the glandular tissue. The tumour situated in the middle of the isthmus was calcified, and when removed was of the size and shape of an almond. A large tumour extending for some distance behind the sternum, the outline of which could not be felt before the operation, was also excised; it measured two inches in length, one inch across, and was partly calcified. The rest of the tumours removed varied in size from a pea to a large hazel nut, and were more or less rounded in outline. Thirteen in all were removed. (Fig. 1.) Several tumours in the left lobe could be easily made out, but it was thought better to defer their removal till another time in case the functions of the thyroid should be too far disturbed by further operation. There was not much bleeding during the operation, but several veins and one or two small arteries required ligation.

The microscopic examination of one of the tumours excised showed it to consist of an outer wall of fibrous tissue. At one part this wall was of considerable thickness and was infiltrated with small round cells. The interior of the cyst was composed of a number of spaces of various sizes, filled for the most part with a colloid material. These spaces were lined by cubical epithelium, and between them there was a small quantity of fibrous tissue; at one part there was extravasation of blood.

The after-course of the case needs no remark. A small drainage-tube was retained in the wound for thirty-six

FIG. 2.

Diagram showing the relative positions of the tumours in the left lobe of the gland.

hours, and the dressings consisted of absorbent cotton-wool covered with a few layers of gauze. The patient made an uninterrupted recovery and left the hospital on April 17th, having been greatly relieved by the operation.

The patient was readmitted on Oct. 23rd for the purpose of having the cysts removed from the left lobe. She had much improved in general health and expressed herself as having been much better able to perform her duties as a domestic servant since the operation. There was no change in the appearance of her face, which remained oedematous and swollen-looking, though it was not really oedematous, did not pit on pressure, and did not vary in size. The right lobe and isthmus of the thyroid were normal in size, the cicatrix was pale and supple, and the left lobe of the thyroid appeared less than six months before. This lobe contained, however, a small mass, not prominent and rather ill defined, and apparently divided into two parts, each part about one-third of an inch in diameter. There was no pain or tenderness. The swellings were elastic and situated at some depth in the gland tissue. On Oct. 30th an incision was made over the left lobe nearly parallel with the edge of the left sterno-mastoid, and four cysts were removed from the left lobe. Two of the cysts occupied the lower part of the lobe and were close together; these were what had been felt through the skin. Two other cysts were detected during the operation; one was opposite the isthmus, and the other and smallest was situated somewhat higher. (Fig. 2.) This latter was reached by cutting through the posterior wall of

the cavity from which one of the other tumours had been removed, and it was found resting on the larynx and separated from it only by a slender layer of thyroid tissue. The lower part of the left lobe was transformed into a cavity bounded by a thin layer of gland tissue. Some venous hæmorrhage was arrested by forceps and hot sponges, and the edges of the wound were retained in position by silk sutures. Dry dressings and a figure-of-eight bandage were applied. She made an uninterrupted recovery and was discharged well on Nov. 13th. The tumours varied in size from a cob nut to a cherry, and were of the same general adenomatous character as those removed at the first operation.

CASE 2. Large cystic bronchocoele; excision of the cyst. (For the notes of the case we are indebted to Mr. Black, the dresser.)—A young woman eighteen years of age was admitted to the Middlesex Hospital, under the care of Dr. Douglas Powell, on Oct. 13th, 1894. Her family history was good; a cousin had a "swelling in the neck." The patient had a slight attack of rheumatism in July last, and had suffered from biliousness, indigestion, and constipation. About three years ago she first noticed a swelling in the front of the neck, which grew in two years to the size it had attained when the patient was admitted into the hospital, and its growth had since been nearly stationary. The patient was subject to palpitation on taking exercise, and had felt pain on taking solid food. She was treated for a month in hospital for anæmia and constipation, and was much improved in both respects; she was then transferred to the surgical ward for operation. The thyroid gland was the seat of an oval-shaped elastic tumour the size and pretty well the shape of a large lemon situated to the left of the median line. The swelling was very elastic and pulsated. The overlying skin was natural and there was neither pain nor tenderness. On deglutition the tumour moved more laterally than vertically. There was no marked prominence of the eyeballs and Græfe's sign was not obtained. The pupils reacted to light. There was occasional dyspnoea, and for this reason as well as because of the unsightly appearance of the swelling the patient desired an operation. On Nov. 14th she was anaesthetised and a vertical incision about three and a half inches long was made in the middle line of the neck, extending to within half an inch of the sternum. The skin and cervical fascia were divided and the muscles drawn aside, when a large globular swelling of the thyroid presented itself through the wound. The capsule of the thyroid and a layer of glandular tissue were divided, and the outer wall of the cyst was then exposed. The complete enucleation of the cyst from within the substance of the gland was effected partly by a blunt raspatory, partly by the finger-nail, and in places, where the connexions were tough and fibrous, by the scalpel. Towards the end of the shelling-out process the cyst wall gave way and several drachms of nearly colourless colloid material escaped. The opening in the sac was closed by forcipressure forceps. There was very little bleeding during the operation. When looking into the wound after the removal of the cyst nothing was seen but a very large recess or bag composed of the left lobe of the thyroid gland, the wall of which in the inner aspect was greyish and purplish in colour and tough and fibrous in texture. In places this wall was very thin, and the trachea and large cervical vessels could be so readily felt through the posterior part that during the operation it seemed that there was really nothing between the back of the tumour and these structures. Such, however, was not the case, as the cyst had a complete investment of thyroid capsule and gland tissue. The thin membranous sac of thyroid tissue was dropped back into the wound and a drainage-tube was inserted into the cavity in the thyroid. The muscles and fascia were then replaced in position and the skin wound closed by silk sutures. The cyst, when laid open, contained some adenoid tissue and a large quantity of mucoid fluid resembling black coffee mixed with coffee-grounds. It was accidentally thrown away before microscopic examination could be made of it. The patient was very sick from the anaesthetic for twenty-four hours, and there was an abundant discharge of thin colloid fluid for the first three days after the operation. On Nov. 17th the pulse rose to 110 and the temperature to 101° F., and she complained of headache. The drainage-tube had been discontinued, so several stitches were removed and the union of part of the wound broken down, when a few drachms of brownish venous-looking fluid and a little thin pus escaped. For the next two days the temperature was between 102°·4° and 100°·4°, then it fell, the discharge diminished, the wound healed, and she was discharged quite well on Dec. 19th last.

Remarks by Mr. HENRY MORRIS.—These cases show the advantage of the treatment by excision. A few years ago the first of the two would have been either left alone, or a part or a whole of the thyroid gland would have been excised; whereas the second case would have been treated either by incision and drainage, or by injection. It would have been impossible by any other means than enucleation to have dealt effectively with the multiple tumours in Case 1. To have excised part of the gland would only have attacked half or less of the disease, the tumours in the remaining portion would still have caused annoyance and deformity, nor would they have stopped growing. To have performed total thyroidectomy would have probably induced myxoedema; whilst to have attempted the destruction of the several tumours by incision and scraping—as has been proposed for some of the larger cysts—would have been tedious and dangerous, from hæmorrhage. Case 2 shows the advisability of dissecting immediately down upon the cyst capsule before attempting removal; by so doing the tumour can be excised without much hæmorrhage and without fear of wounding the recurrent laryngeal nerve, the trachea, pharynx, or œsophagus, or any of the vessels of the neck. There is next to no disturbance of the cellular tissue planes of the region, and the cavity which is left to be closed up is entirely in the substance of the thyroid itself. The wounds after these operations heal very readily, there is not the risk of the severe and dangerous suppuration which sometimes follows the injection treatment, nor is there the inconvenience of a prolonged fistulous opening with discharge going on for months or a year or two, as there has been after the incision and drainage treatment. Some of the serious consequences which have followed excision of large cysts of the thyroid would have been avoided had simply enucleation been adopted. It is a question how far the peculiar œdematous-looking face of the first patient was dependent on the impaired function of the gland owing to the extensive disease.

BRADFORD INFIRMARY.

CASE OF BULLET WOUND OF SMALL INTESTINE; LAPAROTOMY; RECOVERY; REMARKS.

(Under the care of Mr. W. LAKE ROBERTS.)

WITH regard to the subject of gunshot injuries of the abdomen we owe much to American surgeons, who have done a great deal to advance the treatment of bullet wounds of this region. We are not often called upon to treat a case like that recorded below, nor, indeed, are many to be found in surgical literature, the damage done by the bullet being unusually extensive. Early operation, careful suturing, asepsis, and the condition of the bowel are factors which probably conduced to a successful result. The question of interference in gunshot wounds of the abdomen is still discussed, but there is little or no doubt in the minds of those who are engaged in active work, and best able to judge, that operation should be performed. It has been doubted if there is one incontestable instance of recovery from bullet wound of the small intestine without operation; and of all penetrating gunshot wounds of the abdomen nearly 88 per cent. are fatal. There was, therefore, a strong reason for trying some more successful method of treatment, and coliotomy with suture of any intestinal wound will often afford the best prospect of a good result. In 1889 Morton estimated the mortality after operation at 60 per cent.; but this estimate probably includes amongst the number cases in which peritonitis of septic nature was already present, also cases in which there was considerable shock and perhaps loss of blood to diminish the patient's chances of recovery. For the notes of this case we are indebted to Dr. Wood, house surgeon.

A short, slightly built man twenty-six years of age was admitted to the Bradford Infirmary on May 2nd, 1894, with the following history. The patient was struggling with another man in a public-house brawl when his opponent discharged a revolver, wounding him in the abdomen. On admission he was conscious, and there was only a small amount of collapse. The pulse was 88, increasing to 115 at the time of the operation. He complained of nausea. Half an inch below and to the left of the umbilicus was seen a small penetrating wound, the edges of which were bruised.

but not burnt or blackened by powder. There was slight external hemorrhage. Ether having been administered (about four hours after the receipt of the injury), a vertical incision four inches long was made through the wound. As soon as the peritoneal cavity was opened a quantity of blood was seen; this was found to be coming chiefly from a wounded mesenteric vessel, which was secured and ligatured. No fecal extravasation into the peritoneal cavity was found. The intestine was now carefully examined throughout its length, and was found to have been perforated in four places (making eight wounds); there were also three wounds of the mesentery. The wounds were distributed throughout the length of the small bowel. The perforations of the bowel wall were closed by fine silk Lembert's sutures, and the mesenteric wounds were also sutured. The bullet was discovered lodged against the wall of the bowel at its junction with the mesentery; it was cylindrical in shape, 7 mm. in diameter, and weighed 125 gr. The abdominal cavity was irrigated with hot boric acid solution and sponged out as dry as possible. The abdominal wound was closed by catgut sutures into the peritoneum and silkworm gut sutures passing through the whole thickness of the abdominal wall. A small drainage-tube was inserted superficially, but there was none into the peritoneal cavity. The operation lasted 125 minutes; at its close the patient was much collapsed. The pulse was 146. During the first three days after the operation the patient's condition was critical, much anxiety being caused by almost incessant bilious vomiting; this moderated on the fourth day and ceased on the fifth. The pulse-rate was then 74. There was never any distension of the abdomen, and the temperature at no time rose above 99.2° F. Nutrient enemata and suppositories were given regularly from the time of the operation until the eighteenth day, when feeding by the mouth was commenced. The bowels acted slightly on the third day and freely on the fourth day after administration of an enema. The wound in the abdominal wall suppurated, owing doubtless to the contusion, and was not healed until the twenty-eighth day. The bowels were at that time acting naturally every day, and the patient was allowed to get up. He was discharged cured on June 19th. He was seen two months subsequently to this and seemed to be quite well and was free from pain.

Remarks by Dr. WOOD.—There is one point about the case which is, I think, of considerable importance, and that is the empty condition of the bowels at the time the injury was received. The man had been drinking more or less all day, but had taken very little food, and there can be no doubt that this was an important factor in the successful issue of the case, as had the intestines been full of liquid material fecal extravasation would almost inevitably have occurred, which would have greatly increased the gravity of the patient's condition.

EMSWORTH COTTAGE HOSPITAL.

CASE OF ANOREXIA NERVOSA; NECROPSY.

(Under the care of Mr. LOCKHART STEPHENS.)

MANY of our readers will recollect the case of this disease which was published in THE LANCET of March 17th, 1888, and the illustrations here given will recall one of those then depicted. The case to which we refer was one under the care of the late Sir W. Gull, and attracted much attention at the time. In a leading article we summed up the symptoms of the condition, and cannot do better than reproduce what is there written: "The patients are generally young girls from fourteen and upwards, though we have known a striking case at a much earlier age. The disease may, however, occur in males. The great feature of the cases is complete anorexia, leading to extreme emaciation, with slow pulse, subnormal temperature, and very few respirations. Strange to say, there is associated with these depressed functions a remarkable restlessness, a disposition to be moving or walking about, though the patient is an object of remark in the street. There is an entire absence of signs and symptoms of tuberculous or other organic disease." The disease does not often prove fatal; therefore, the following case, which by the way confirms our last remark, is of considerable importance.

A girl sixteen years of age was admitted to the Emsworth Cottage Hospital on March 10th, 1888, on account of extreme emaciation. On admission the patient was a tall

intelligent girl of fair complexion and hair, with a somewhat sad expression, resembling strongly (as in Dr. Stephen Mackenzie's case¹) the diabetic face. She was rather affected in her manner and at times almost childish in her conversation. Her limbs and body, if properly nourished, would have been well developed; the breasts alone took no share in the extreme wasting, but stood out in marked contrast. She weighed 56 lb. Repeated and careful examinations failed to detect any signs of disease in the thoracic or abdominal organs. The bowels acted every other day. The urine, sp. gr. 1018, was acid, without a trace of albumen, sugar, or other abnormal constituent. The teeth were good, the tongue was clean and red, the abdomen markedly retracted (there was no pain on manipulation), and the lips were fissured from a habit of constantly licking them with her tongue. Though there was no marked aversion to any particular kind of food she preferred sweets and dainties, but would not take more than a most minute portion at any time. Up to ten months previously to admission the patient had been a remarkably well-made, plump, and healthy-looking girl, full of spirits and eager to attract the notice of her friends, which she did to a considerable degree, becoming a favourite with her teachers and others. Gradually, and from no apparent cause, she showed a disinclination to take the same food and at the ordinary meal times as the rest of the family. This went on until she reached the very emaciated state in which she was on admission; but even then she persistently maintained that she was quite well and resented being placed under treatment. She was able to help her mother in her household duties, but preferred taking long walks when she had the opportunity, apparently without feeling fatigued even after walking long distances. Her father and mother were living and healthy, though the latter was very excitable and quite under the influence of the patient, who was the only girl out of six children and the spoilt child of the family.

Remarks by Mr. STEPHENS.—My first impression, before examining the urine, was that I had to deal with a case of diabetes, yet of this I was very doubtful, never having seen in diabetes, or in any other disease associated with wasting, so much physical strength in such an ill-nourished body. Finding no symptom but wasting, I came to the conclusion that the case was one of "voluntary starvation" in an otherwise healthy subject. I had not then read the late Sir William Gull's paper,² or his case recorded in THE LANCET of March 17th, 1888. As the girl was under no control whatever at home I advised her parents to allow her to come into the Cottage Hospital on the distinct understanding and promise that whatever treatment was thought necessary should be carried out. She was ordered to be kept in bed with her limbs and body bandaged in cotton wool, to be fed every four hours with peptonised food, and to do nothing in the way of exertion. At first no difficulty was experienced in managing her, but after a few days she resented all treatment, became sullen and fretful, crying out for her mother, who lived only a few doors from the hospital, the result of which was that her mother, in spite of advice to the contrary, persisted in seeing her every day. From this time she began to lose the little ground we had gained; she took very small quantities of food, and resorted to every conceivable trick to avoid swallowing it, although she would take it into her mouth. On April 1st she was able to get out of bed and walk round the room without difficulty. On the 2nd (6 A.M.) the nurse noticed that she was much weaker, and could only with difficulty swallow some egg-and-milk. At 8 A.M. she was rather brighter, but at 8.45 A.M. she became suddenly collapsed, and when visited a few minutes later her condition was as follows. She was in a position of extreme helplessness, the eyes were fixed, the pupils dilated and insensitive, and the conjunctivæ insensitive. The respiration was 12, the temperature 96° F., and the pulse 60, not being perceptible in the radials or the posterior tibials, and very feeble in the axillary and femoral arteries. The extremities were livid, cold, and clammy; the breath was cold and emitted a death-like odour. Hypodermic injections of brandy (fifteen minims) were given every ten minutes; hot flannels were applied to the epigastric region and hot bottles to the feet, hand, axillæ, and trunk were in turn applied. In about twenty minutes the pulse became stronger and could be felt at the wrists. No very marked improvement took

¹ THE LANCET, March 31st, 1888.

² Clinical Society's Transactions, vol. vii., p. 22.

place until 11 A.M., when in order to get more warmth (the extremities and trunk being now warm, but the breath cold) an œsophageal tube was passed and about ten ounces of milk as hot as could be borne in the mouth administered. Almost immediately the respiration became stronger and deeper, and shortly after she showed signs of consciousness, so that at 11.40 A.M. she was able to speak and to understand what was said to her. During the afternoon she

FIG. 1.

was able, unassisted, to raise herself on her shoulders and heels to allow a drawsheet to be removed. Shortly after midnight it was noticed that the respiration was becoming more frequent and more shallow. This continued to increase, and sinking rapidly she died at 2.30 A.M. on April 3rd.

Necropsy, made at 10 a.m. on April 5th, fifty-six hours after death.—The body weighed 49 lb.; the height was 5 ft. 4 in. The circumference of the arm high up at the shoulder was 4½ in.; circumference of the wrist, 4¼ in.; circumference of

FIG. 2.

the waist, 17 in.; circumference of thigh just below the great trochanter, 8 in.; circumference of the neck, 8½ in. The body was extremely emaciated; there was not a trace of fat in the subcutaneous tissue with the exception of the breasts, which stood out boldly. On opening the abdomen there were visible: the lower edge and anterior surface of the right lobe of the liver, measuring three inches and a half vertically; the anterior surface of the stomach for two-thirds

of its extent, starting from the pyloric end, which was below the level of the umbilicus, so that the long axis of the organ was directed almost vertically downwards; three inches of transverse colon just above the pubes, in the great omentum. The bones of the head were thin, the membranes and vessels were normal, and the brain was normal throughout; it weighed 45½ oz. The right lung weighed 19 oz. (it was much congested from hypostasis). The left lung weighed 11½ oz.; it was less congested than the right. Both lungs were otherwise normal. The left pleural sac contained about ¼ oz. of clear serum. The heart weighed 4 oz.; its external appearance was normal. Both auricles contained small decolourised clot. The left ventricle was firmly contracted; the right was thin and flaccid; the valves were healthy. The liver weighed 23½ oz.; it was normal in appearance. The gall-bladder contained one drachm of clear, thin bile. The pancreas (weight 1½ oz.), spleen (weight 1½ oz.), adrenals (weight of each ½ oz.), and kidneys (weight of right 3 oz., of left 2½ oz.) were all normal. The uterus and ovaries together weighed ½ oz.

Medical Societies.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

Exhibition of Cases.—Raynaud's Disease.—Intestinal Obstruction.

A MEETING of this society was held on Dec. 19th, 1894, Dr. CLOUSTON, President, being in the chair.

Mr. CATHCART showed two patients illustrating Ulcerative Forms of Secondary Syphilis. He remarked that, although, according to Mr. Hutchinson, rupee was not confined to the tertiary period, it might be important, medico-legally, to note at what period ulcerative processes might occur. The first case, a lad, had acquired syphilis in July, had a well-developed sore in September, and in December had a most typical rupee, a cast of which was shown. The sores now showed deep ulceration in a healing stage. The hard sore had left no scar. The second case showed severe ulceration of the throat, though there was no history of alcoholism or evidence of specially weak constitution.—Dr. JOHN THOMSON showed a child with Congenital Absence of the Pectoral Muscles on the left side and deficient development of the left forearm.—Dr. W. ALLAN JAMIESON showed a case of Molluscum Contagiosum. On the left side of the face were several mollusca the size of a pea, and there was a patch behind the ear where the tumours had become aggregated. There was at the back of the knee a tumour which had originally been a wart, and had taken a molluscous growth. The case resembled some cases of Darier's disease.

Dr. URQUHART read a paper on two cases of Raynaud's Disease. The first case was that of a man thirty-three years of age with a very rheumatic history. There was no history of syphilis, but for some years previously he had been addicted to intemperance. Some months previously to coming under Dr. Urquhart's care he had had a severe attack of enteritis, after which the mental condition deteriorated. He had very severe headaches, loss of memory, and general mental weakness. The enteritis recurred, and as delusions supervened he was put under Dr. Urquhart's charge in the Perth Asylum. He was then found to be anæmic and constipated. The reflexes were normal except the pupils, which were sluggish. He was very taciturn; when he did speak his utterances were foolish. There was considerable excitement, with resistance. He had delusions. Hæmatoma auris developed. Nourishment was taken badly. Shortly after admission the feet became black up to the ankle, hebetude became marked, and retention of urine developed. The feet improved slightly for a time, but never lost the dusky colour. The improvement only lasted for a short time, when the colour deepened and the features became pinched. No pulsation could be made out in the posterior tibial arteries. Shortly afterwards the patient died. Post mortem the lungs were found congested, with cavity formation at the apices. The right kidney was found to be normal; the left was tuberculous. The brain convolutions were atrophied. The ventricle contained a large amount of fluid. In the feet the vessels of the skin were engorged and in a condition of stasis. There was no neuritis present. The

bone marrow showed diapedesis. The anterior and posterior tibial arteries and nerves were normal. The medulla and pons were normal. There was not the interstitial change in the affected parts found in ordinary gangrene. The second case was that of a woman who had influenza in 1892, after which she became melancholic. As she became subject to delusions she was sent to the asylum. From February, 1892, the mental condition remained much the same. There was retention of urine from time to time, with a transient albuminuria. She developed hæmatoma auris. She was very sensitive to cold. Some time after this the feet became swollen and blue. Patches of a brown colour appeared, and the colour of the feet deepened. The skin roughened and began to peel off. After three months' confinement to bed she began to improve and was able to get up, but in a fortnight the blueness recurred. This had happened several times since. Dr. Urquhart thought in those two cases the malady was central in origin. Both had hæmatoma. Neuritis had been found in some cases, but seemed to be more a complication than an essential factor in the disease. The nerve should be examined above and not at the point where it was implicated in the diseased part.—Mr. JOSEPH BELL said that the paper had been very instructive as an interesting clinical study, but he was no wiser as regarded the question of amputation. He thought from a surgical point of view masterly inactivity was the proper treatment.—Mr. CATHART did not think it possible to exclude vascular obstruction in the first case simply because the tibial arteries were not affected. He had often examined legs showing gangrene low down in the foot, and had found the seat of obstruction at the bifurcation of the popliteal artery.—Dr. BRUCE had examined one case where the toes were amputated for gangrene. There was distinct closure of the arteries, the intima being united, leaving only a longitudinal cicatrix. He quite agreed that neuritis might be the result and not the cause of the disease. He did not think they had yet found a cause adequate to account for the chronicity of the disease.—Mr. ALEXIS THOMSON said in one case he examined he did not think the neuritis could be secondary, though he did not say it was the primary cause. In a second case he had found very little evidence of neuritis. Amputation should only be done to rid the patient of dead tissue.—Dr. Urquhart replied.

Dr. JAMES RITCHIE read a paper on a case of Intestinal Obstruction. The patient had been first seen on Sept. 18th, when he was suffering from diarrhoea and vomiting. The tongue was thickly coated, there was troublesome flatulence, and the abdomen was somewhat distended. Under treatment the sickness and diarrhoea ceased and the appetite returned. At the commencement of the following week there was a return of the gastric catarrh and the bowels became constipated. Some improvement took place, but on the 29th severe hæmatemesis with some fever came on. Efforts were made to empty the bowels, but without effect, and the abdomen became distended. The case being viewed as one of a septic condition of the bowels, with consequent paresis of the intestinal walls, salol and purgatives were given. On Oct. 4th there were several copious pultaceous motions, and the condition improved. Soon, however, the epigastrium became prominent from distension, and a small movable nodule was palpable to the left of the umbilicus. The bowels were again constipated, and inspection revealed peristaltic movements of the bowels. Obstruction due to a malignant tumour was diagnosed. The rectum revealed ballooning, but no tumour or tenderness. Fully three pints of water could be injected; therefore probably the obstruction was not at the sigmoid. From Oct. 4th no satisfactory motion was obtained and the general condition deteriorated. On the 27th Mr. Chiene saw the patient, and decided to operate on the following day if no improvement took place. During the day the patient became suddenly worse and died from heart failure. Post mortem a flattish mass about the size of a dried fig was found in the great omentum to the left of the middle line. The ascending and transverse colon was much distended. At the splenic flexure there was a hard mass, which completely encircled the gut and caused great narrowing of its lumen. Dr. Ritchie then reviewed the literature and interesting features of the case, and advised the use of intestinal antiseptics, combined with enemata, in cases of chronic obstruction.—Mr. JOSEPH BELL said he had met a somewhat similar case last week. A woman between sixty and seventy presented symptoms of chronic obstruction. There was no trace of anything per rectum, except ballooning. The lower bowel

daily admitted three or four pints. She never had vomiting. Three weeks before death she passed what she stated was an excellent, large, firm stool, about which, however, he had some doubt. The abdomen was distended, the colon being visible. Flatus was easily passed, and faecal matter, but not in large quantity. On opening the abdomen no tumour could be felt at the sigmoid, but at the cæcum a very strong band binding it down completely was discovered. This was divided. Great relief followed, but the transverse colon did not quite empty itself. He advised an artificial anus, but the friends objected. After operation flatus was easily passed, but no large stool. The patient died suddenly from heart failure. Post mortem they found a small, tight, cancerous stricture in the sigmoid flexure, which Dr. Boyd reported to be a slowly growing carcinoma with colloid degeneration.—Mr. HODSDON said he had had a very similar case on the previous Friday. The difficulty always was to find the point of obstruction in order to know where to open. He opened on the left side and found a very small stricture. He was led to open on the left side from distension of the intestine and the smallness of the enema which could be admitted. He thought that in chronic obstruction in old people an artificial anus should always be made. It did not cause much inconvenience. He had one patient where this was done who was now working as a labourer.—Dr. RITCHIE replied.

Reviews and Notices of Books.

Clinical Lectures and Essays on Rickets, Tuberculosis, Abdominal Tumours, and Other Subjects. By Sir WILLIAM JENNER, Bart., G.C.B. London: Rivington, Percival, and Co. 1895.

THERE is no doubt that this volume of Sir William Jenner's collected writings will be as heartily welcomed as was the republication last year of his memorable essays upon Fever and Diphtheria, and many will feel indebted to him for the opportunity of possessing them in a permanent form; indeed, we question whether there are many now in practice who have ever read those masterly lectures upon Rickets which appeared in the columns of the *Medical Times and Gazette* thirty-five years ago and are now for the first time reprinted. The same applies to the lectures on Tuberculosis which follow. These two courses of lectures were delivered in the Hospital for Sick Children, Great Ormond-street, and although a generation has passed since their delivery they are still full of instruction, for they were the product of a keenly observant mind and are stamped with the individuality of their distinguished author. The lectures on Rickets stand out pre-eminently as the foremost contribution to our knowledge of this common disease. To Sir William Jenner must be accorded the great merit of clearly seeing the truth that this disease was, as he puts it, "no more a disease of the bones than is typhoid fever a disease of the intestines." He established it as one of the four diatheses to which infantile life is prone, and at the outset of his lectures concisely contrasts the leading characteristics of these four—tuberculosis, scrofulosis, rickets, and syphilis. In reprinting the lecture he has adhered to the distinctions laid down in the text: they were differences which for him were definite and unalterable, types of morbid conditions which could never be confounded. Therefore it is that he says in the brief prefatory words to this volume: "I have not altered the paragraphs relating to the difference between scrofula and tuberculosis. For although recent histological researches have shown the identity of their ultimate pathological products, yet I still hold that the constitutional states which precede the local manifestations are of a different type in these two disorders and deserve separate consideration." Nor does this retention of conceptions which have been to a certain extent swept aside by the pathological investigations of these latter days in any way detract from the value of his testimony. For the fidelity of

his descriptions must remain, and although we can no longer say, as he did, that "syphilis and tuberculosis are undoubtedly not identical because syphilis owes its origin to a specific cause and tuberculosis does not" (p. 8), yet we must all recognise the clinical and pathological distinctions which are here so tersely given. Coming now to the main substance of these lectures on Rickets, the reader cannot fail to be struck with the care and accuracy with which the various morbid states inherent to it are described—the skeletal lesions and the deformities to which they give rise, the stress laid upon the effect of pressure as a potent factor in the production of limb and thoracic deformity, and many other points that are dealt with in strictly scientific method. Sir William Jenner assigns considerable importance to the condition which he terms "albuminoid infiltration" of the viscera, notably the spleen, liver, and lymphatic glands, in this disease. This term, which unfortunately was at one time used synonymously with the totally different condition of amyloid infiltration, has fallen into disuse and in current writings we hear but little of it. Yet that there is enlargement of these organs in rickets, and that it is probably associated with the concomitant anæmia, is undisputed. We could fain wish that histologists would tell us whether the state of the organs in question is more appropriately denominated a hyperplasia than an infiltration, but we are not aware that they have done so. In clinical description there is little in literature to equal that which is given in the lectures on Rickets. What, for instance, can match the following as a piece of word-painting thoroughly true to nature:—

"A child in health delights in movements of every kind. It joys to exercise every muscle. Strip a child of a few months old and see how it throws its limbs in every direction; it will raise its head from the place on which it lies, coil itself round, and grasping a foot with both hands thrust it into its mouth as far as possible, as though the great object of its existence at that moment was to turn itself inside out. The child suffering severely from the general cachexia which precedes and accompanies the progressive stage of the bone disease ceases its gambols, it lies with outstretched limbs as quietly as possible, for voluntary movements produce pain. Its unwillingness to be moved is so great that, as Stiebel has observed, it will cry at the approach of those who have been accustomed to dance it, of those at the sight of whom it previously manifested extreme pleasure. As the disease progresses the child gets a peculiar staid and steady appearance; its natural lively expression is replaced by a pensive, aged, languid aspect; its face grows broad and square; and when placed upright on its mother's arm it sits, as she says, 'all of a heap.' Its spine bends and its muscles are too weak to keep it erect. Its head seems to sink between its shoulders; its face is turned a little upwards. And now the consequences of the bone disease are superadded to the general derangement. It is strange to see a little child sitting placidly on the bed without moving for hours together, its legs placed so as to escape pressure, its spine bowed, its head thrown backwards, the chief weight of its body cast upon its anus; and to know that, notwithstanding the apparent calm, the tiny thing is indeed fighting the battle of life, for it is striving with all the energy it has to keep in constant action every one of its muscles of inspiration, endeavouring so to supply the mechanical defects of its respiratory apparatus due to the softening of the ribs. It wants no toys. It is the best of children if you only leave it alone; move it and you inflict pain on its tender frame; show it the horse or the doll that was once its delight and it turns away its head or stares vacantly; to notice would divert its attention too much from the performance of those respiratory movements which are essential to its existence" (pp. 37-39).

It is when reading passages like these—and there are many such within the covers of this book—that we appreciate the author's keen powers of observation and also his power of imparting to others what he himself observed. We can

understand the better his unique aptitude for clinical teaching, and the enthusiasm, akin to reverence, with which those who were privileged to be his pupils recall the instruction he gave by the bedside. It makes us regret all the more keenly that owing to the imperious demands of practice he should have given us comparatively so little in published form.

The two lectures on Tuberculosis complement those on Rickets and convey the like impression of the author's characteristics. The first lecture opens with a warning against making a specialty of the diseases of children and drives home the lesson by a happy comparison between infancy and age as regards their respective tendencies to morbid lesions. Then follows a striking description of the physiognomy and build of the child who is the subject of inherited tuberculosis, much stress being laid on its small lung capacity. The type is as familiar to-day, when doubts are freely held whether tuberculosis is really inherited *per se*, as it was when these descriptions were penned by one who held that "the germ anterior to the formation of the blood, and even before it has divided into parts, is the subject of tuberculosis" (p. 75). After all, the problem of heredity, and the transmission of a special conformation of body, is unaffected by the alterations in the standpoint of thought as to disease: it is merely a change of idea as to the transmission of the disease itself or, rather, of the proclivity to it. The lecture then goes on to describe the various forms under which acute general tuberculosis affects the child. These forms are enumerated as: (1) the insidious, (2) the active febrile, and (3) the adynamic. The statement that acute tuberculosis is not a necessarily fatal disease, but that "recovery from it is very common," is justified by an appeal to the facts of observation in the post-mortem room, where old obsolescent tubercle is so frequently found side by side with recent lesions. The second lecture deals with tuberculosis of lymphatic glands, especially mesenteric and bronchial. A quotation will best convey the position assumed [on this subject, which involves the vexed question of the nature of scrofula:—

"There are some great facts I desire by all this to impress on the mind of the youngest of my hearers—viz.: 1. That primary inflammation of the lymphatic glands is a very rare disease, even in scrofulous children. 2. That secondary inflammation of the superficial lymphatic glands is a very common disease. 3. That a superficial lymphatic gland being in a state of active congestion, by seeking out and treating the primary lesion, we can in all but every case prevent the occurrence of suppuration of the gland. 4. That when a superficial lymphatic gland inflames and suppurates without there being inflammation of the tissues from which the lymphatics to the gland lead, in almost all, if not in all, cases the gland so inflaming is the seat of the deposit of tubercle. 5. That the lymphatic glands of scrofulous children, and glands which contain tubercle, inflame and suppurate from an amount of irritation which would merely lead to moderate active congestion of the glands in a child of healthy constitution" (p. 91).

The volume also contains the article upon Emphysema of the Lungs which Sir William Jenner contributed to "Reynolds' System of Medicine," an article which is notable for the remarkable clearness of exposition and the force of its argument in support of the expiratory theory of the production of the condition. His paper in which he first set forth this doctrine before the Royal Medical and Chirurgical Society is also given. Many will turn to the lectures upon Extra-pelvic Tumours of the Abdomen in anticipation of most valuable clinical instruction. Nor will they be disappointed. These lectures, delivered at University College Hospital, were reported at the time of delivery by Dr. Gowers and afford a good example of Sir William Jenner's teaching. They do not cover the whole ground of abdominal tumours, but they are full of acute remarks which are of real practical value. We cannot refrain from another quotation, in which, in introducing the subject to his class, he

speaks of the aims and methods of clinical teaching. It runs as follows:—

"Now, clinical teaching should enable the student to start from a higher point of experience than he could attain by his unaided powers. The knowledge which the teacher has acquired by the practice of his profession should be to a considerable extent imparted to the scholar. The clinical scholar should be taught by his master to see with his eyes, to touch with his hands, to hear with his ears, to reason with his brain; he should, in fact, be put into possession of that practical knowledge which in long time the master has acquired for himself, and should be by his master's aid possessed of the method by which practical conclusions from facts observed are to be drawn. At the end of his pupil career, then, you will see, the clinical scholar should start from a vantage ground, and not only should he start from the practical position his teacher has gained, but should also have been trained to use his senses so as to gather real facts for himself, and to use his reason so as to draw sound conclusions, to make every case which he subsequently sees add to his real practical knowledge. When he attends a case, even though it be of the commonest disease, he not only sees the case, but he learns something, adds something to his experience" (p. 216).

In addition to the subjects already mentioned the volume contains papers and extracts from clinical lectures on such matters as Deformities of the Chest, Hysterical Laryngitis, Congestion of the Heart, Sarcina Ventriculi, and the observations on "Burnt to Death" which Sir W. Jenner a few years since contributed to the columns of THE LANCET. The book is dedicated to his old pupils, and they will indeed appreciate its publication. But the profession at large will be glad to have for perusal the writings of one who in his day did so much to advance the science of medicine and to uphold the purity of its practice. It may truthfully be said that in his retirement he bears with him the enduring esteem and gratitude of the large body of men who have profited by his teachings and example.

Fibroid Diseases of the Lung, including Fibroid Phthisis. By Sir ANDREW CLARK, Bart., M.D., LL.D., F.R.S.; W. G. HADLEY, M.D. Durh., M.R.C.P.; and ARNOLD CHAPLIN, M.D. Cantab., M.R.C.P. London: Charles Griffin and Co. 1894.

ONE of the most striking characteristics of the lamented physician whose name stands first on the title-page of this volume was the enthusiasm with which he adopted and the fervour with which he upheld doctrines that seemed to him to be right. It is somewhat difficult now, when, alas, we have him no longer with us, to realise the stir that was made in pathological circles by his enunciation of belief in "fibroid phthisis" as a substantive disease of the lung, having a definite etiology and course distinct from chronic phthisis of tuberculous origin, with which occasionally the former was intermingled. It seems strange that the question should have been so ardently discussed, and that in a matter of this sort there should have been so much room for differences of opinion. In a sense the use of the term "phthisis" was the pivot around which controversy raged; but there can be no doubt that it was largely due to the fervid nature of Sir Andrew Clark himself that the question was raised out of the common level of dry pathological fact. We believe it was on the occasion of his paper on the subject, read at the Clinical Society in 1868, that the controversy in question attained its full development. That paper is reproduced in the present volume, and, reading it anew, we cannot but be impressed by the clinical and pathological zeal of its author and his absolute freedom from the current tendency of the day towards the restriction of the term "phthisis" to tuberculous disease alone. Thus he wrote: "It is plain, then, from what has been said, that to employ the term 'tubercle' in a 'comprehensive sense'—that is, in a sense depriving it of any definite meaning, and to maintain, as so many distinguished persons still strive to do, the unity of phthisis, is to reject the most precious results of pathological research, to ignore the distinctions established

by clinical inquiry, to relinquish the hope of a rational therapeutic, and to resign oneself for ever to the guidance of a blind and capricious empiricism."

And a few lines further on he thus justifies his adoption of the term "fibroid phthisis": "In this term the author proposes to embrace all these cases, whether local or constitutional, which are anatomically characterised by the presence, in a contracted and indurated lung traversed by more or less dilated bronchi, of fibroid tissue, and of a tough fibrogenous substance, together with cheesy deposits or consolidations, and usually small cavities commonly found about the middle and lower parts of the affected organ. Several objections may be justly made to the designation proposed; but in the writer's mind they are all outweighed by this great advantage. The name expresses the leading anatomical fact of the disease, and whilst theories of its nature will change the structural character must remain always the same."

We venture to call attention to these earlier statements of Sir Andrew Clark, if only to show, as the publication of the present volume proves, that he never swerved from the doctrine there laid down. The changed light with which, owing to Koch's discovery, tuberculous disease came to be regarded served only to bring out in stronger relief the characters of the morbid pulmonary conditions which Sir Andrew Clark included under "fibroid phthisis." He had, we believe, for long entertained the hope of bringing to the notice of the profession the substance of his observations on this subject; and the lines of the present volume, in the preparation of which he was aided by his former pupils, Drs. Hadley and Chaplin, were planned some time before his death. It comes now as a kind of legacy to the medical world, embodying the mature conclusions of a gifted mind upon a much debated matter. The historical review with which the volume opens gives with admirable precision the opinions and researches of leading authorities from the time of Bayle; and it is at once a tribute to that pioneer in pulmonary pathology, as well as an instance of the tendency in pathological ideas to come round again to original ideas, that the unity of phthisis is still disputed. And if the term "phthisis" is to be retained in the sense in which Bayle used it there can be no question that Sir Andrew Clark was right, both in logic and in fact, in insisting on the inclusion of other than tuberculous disintegration under that term. Often has he impressed this on his friends and pupils, and the words in which he here defines the term have a familiar sound, recalling vividly the personality of their writer. "By this term," he says, "is meant the assemblage, progression, and relation of signs and symptoms, associated with, or dependent upon, the ulcerative or suppurative disintegration of more or less circumscribed non-malignant consolidation of the lungs" (p. 32). This sentence occurs in Chapter II., "On the term 'Fibroid Phthisis,'" in which is to be found an instructive contrast between the larger group of cases of tuberculous phthisis and the smaller group of fibroid phthisis. Chapter III. deals with the pathological anatomy of the subject, and here it may be remarked that the full and ample descriptions of the gross morbid appearances and histological characters of pulmonary fibrosis have an especial value. They demonstrate the fact that "fibroid disease of the lungs," which to our thinking is a far more appropriate term than "fibroid phthisis," may be met with in various degrees and in varying distribution within the lung itself. Commonly unilateral, it may in certain cases—e.g., those due to dust inhalation—be bilateral; often associated with extensive pleural thickening, there yet are cases in which the pleura is comparatively unchanged; sometimes nodular, and then most simulating "obsolescent tubercle," the lesion is more frequently diffuse; whilst it may have caseous masses, and vomicae resulting from their softening, which are to be distinguished from the deposits of tuberculous

origin. Lastly, bronchiectasis—which, according to the type of the disease, may lead to cavity formation, or be limited to cylindrical enlargement—is a very constant concomitant. It seems to us that the clue to these varieties in scope and character of lesion is to be found in the etiological factors, which are enumerated at the commencement of the next chapter, dealing with the clinical features of fibroid disease. And, further, if criticism be permissible, it would be to the effect that it would have conduced to definite and clear notions of “fibroid disease” had the pathological description—so far as this is possible—been treated under the several heads of these etiological factors. To instance only a few examples. The fibroid lung resulting from broncho-pneumonia (averred to be the most common antecedent) is different in many particulars from the rarer state of fibrosis supervening upon lobar pneumonia; and that, again, from the general fibrosis of chronic bronchitis, or of dust inhalation, or the more limited “pleurogenic” varieties. Their common element of interstitial induration is the only link which binds these various states together pathologically, whilst it may even be questioned whether clinically it is not possible to differentiate many of these forms. This, however, by the way, and with no desire to lessen the value of the masterly clinical picture that is sketched in these pages. It is a description that will bear repeated perusal, for without being redundant it brings out the salient features of the case and of its course in a succinct and at the same time striking manner. The chapter closes with an account of some cases in illustration of the clinical description.

The authors by no means ignore the association of tuberculosis with fibroid disease; but they do not enter into much detail in this part of the subject, which is really that of chronic tuberculous phthisis. In the fifth chapter two varieties are described—the one termed “tuberculo-fibroid,” implying that tuberculosis has undergone fibroid transformation—the most hopeful form of chronic phthisis; and the “fibro-tubercular,” in which tuberculosis secondarily involves a lung already fibroid. The frequency with which in the post-mortem room old fibroid change, sometimes of considerable extent, is encountered side by side with more recent caseating or miliary tubercle makes it difficult to be certain that the latter group is really different from the former. If in the one case the fibrous transformation or obsolescence of tubercle is conceded, why not also in the other? The authors, however, lay stress on the fact that the earlier history of the fibro-tuberculous group is that of a chronic affection; indeed, that of “pure fibroid disease,” to which suddenly the signs and symptoms of a rapidly advancing tuberculosis are superadded. The few pages devoted to treatment, which also form part of the fifth chapter, are perhaps the least satisfactory—or rather satisfying—part of the book; but, seeing that the main purpose of the work was rather the description of the natural history of fibroid disease of the lung, the question of treatment may have been intentionally assigned a subordinate place. Chapter VI. is devoted to an analysis of cases, and in the final chapter is reproduced Sir Andrew Clark’s paper read at the Clinical Society to which we have above referred.

It should be added that the volume contains several striking coloured drawings of specimens of fibroid disease (three of which have been published in *THE LANCET*), drawings which are artistic as well as extremely faithful representations of the lesions described. Their value would have been enhanced by more direct reference to them being made in the text. Lastly, the book, as regards type and paper, has been produced in a style which we are accustomed to meet with at the hands of the publishing firm that is responsible for them.

The Prevention of Epidemics and the Construction and Management of Isolation Hospitals. By ROGER McNEILL, M.D. Edin., D.P.H. Camb., Medical Health Officer for the County of Argyll, formerly Resident Medical Officer to the Infectious Hospitals of the Metropolitan Asylums Board at Homerton and Deptford, London, and H.M.S. *Atlas and Endymion*, Greenwich. London: J. & A. Churchill. 1894.

In commencing our notice of this volume we may say at once that we have formed a very definite opinion in regard to it. It is a good and useful work. Dr. McNeill possesses, in the first place, the necessary knowledge and experience to make what he has to say well worth reading; and, in the second place, he has succeeded in expressing himself clearly and to the point on various subjects, to the consideration of which he has evidently given a good deal of thoughtful care. There is no need to dwell upon the loss and misery that infectious diseases so frequently entail, or upon the importance of the measures that should be adopted to prevent or limit the spread of them. All are theoretically agreed, at any rate, in this respect, but practically all do not realise how necessary it is that we should possess clear notions in regard to the nature of the preventive measures that should be adopted and promptly carried out if our attempts in this direction are to be really effective and not unavailing. It is obvious that our efforts should, as far as possible, be concentrated on the initial stages of such diseases while their manifestations are still limited to a few individuals, and before the infection has had time to spread and give rise to an epidemic. It is easy enough to provide for the accommodation of a small number of patients at the very commencement of a threatened outbreak, but it is often difficult, or even hopeless, to attempt to do so for the larger numbers affected in an epidemic. The author is right in saying that the importance of preventive measures has not been sufficiently practically realised in many small towns and rural districts, and it is easy to understand why this should be so. In the principal towns every endeavour has been, or is being, made to cope with the problem as a recognised measure of public safety. But the less populous are only feeders of the more populous centres, and the prevalence of any infectious diseases in the one necessarily endangers the other. Epidemics of disease which spread solely by infection do not cover the whole area of a province or community in their incidence. They begin in one district and spread slowly or otherwise in various directions, or each little centre acts as so many separate foci or depôts of infection to the rest of the community.

The book consists of nine chapters, with an appendix of hospital plans and accompanying descriptions and index. The illustrations are very good, and the relative merits of the various plans may be compared and considered with much advantage by the reader. It is impossible, within the compass of a review, to deal with all the subjects included in Dr. McNeill’s book, and we must therefore content ourselves with a few of the more salient and practical points.

Passing over the first three chapters dealing with the dissemination of infectious diseases and the influence of effective measures against their spread, we come to the chapter which treats of the nature of infection and its influence on the construction and management of isolation hospitals. The antiseptic method has been singularly successful on the surgical side of our hospitals in preventing the occurrence of infective wound diseases, but there is no similar specific method of preventing the micro-organisms of the ordinary infectious diseases from entering the system by the breath or by food or water. It is all the more necessary, therefore, that isolation hospitals should be so constructed, furnished, and managed as to prevent the retention or absorption of any micro-organisms of infection,

and afford at the same time ample superficial and cubic space with a plentiful supply of fresh air. In large towns it has been stated that about one bed per 1000 of the population is a sufficient provision for the isolation of infectious disease to meet ordinary emergencies; but each case must, after all, be considered on its merits, for the number of beds necessary varies in different localities and under different circumstances, and the same may be said as regards the position of the hospital. The distance that patients suffering from infectious diseases may be safely conveyed is a matter to be considered, and the results of experience are well set forth and summarised in the work under review. According to our observation cases of enteric fever are likely to be prejudicially affected by being transported long distances unless their removal can be undertaken at an early stage. The feeling of the population may also be fairly considered to a certain extent in settling the distance patients are to be conveyed to a hospital. The site of a hospital as regards a safe distance from other buildings and thoroughfares in view of guarding against infection may be inferred from the experience gained in the case of various isolation hospitals. There is really very little risk of infection from well-constructed and thoroughly well-managed hospitals. If we exclude small-pox, the rule of the medical department of the Local Government Board may be followed—viz., that no part of the isolation hospital should be nearer than forty feet at least of the area wall. Here, again, local circumstances and the discipline, internal economy, and management of the hospital are important points. In rural districts where land is plentiful and comparatively cheap the site and the area to be occupied by the hospital may be fairly settled by considerations that would not apply to a town. But we may safely say that there is no necessity, from a purely sanitary standpoint, for the erection of isolation hospitals at such long and inconvenient distances from habitations as is frequently the case. Even in the case of small-pox some think that the spread of the disease is in proportion to facilities of communication rather than to an aerial distribution of the infection. It is unquestionably safer, however, to act on the latter assumption. It is obviously important in connexion with these institutions that, if isolation hospitals are of any size, a probationary room or ward should be provided for the reception of cases under observation until the nature of their disease is established. There are a considerable number of other points of interest which we must pass over. As regards the system of drainage, we quite concur in thinking that all the drains should be subjected to the water test, and the contractor should be clearly told that he will be held responsible for any leakage discovered. As regards the provision of connecting covered corridors between the different blocks for the protection of nurses and others against the effects of weather and wet, it may be said that theoretically the separate blocks should be entirely disconnected, and at Glasgow the nurses are provided with overcoats to protect them against the weather. We imagine that practically, however, covered corridors are commonly provided. Some of the plans in the appendix are, as we have said, very good, and they are all very useful for reference.

NEW OVERLAND ROUTE TO THE ORIENT.—An important addition to the routes to Constantinople and Egypt has been made this week. The International Sleeping Car Company has concluded arrangements with the various Continental railway companies and the Administration des Paquebots Poste Khédivie, by which, on Sunday, Jan. 8th, and every following Sunday, a special service *de luxe* will be run through from Ostend to Constantinople without change of carriage. There the passengers will at once go on board the mail steamer, which will leave immediately and go straight to Alexandria.

Analytical Records

FROM

THE LANCET LABORATORY.

(1) BISMUTH SALICYLATE. (2) EASTON'S SYRUP. (3) PEPSIN, BISMUTH, AND CHARCOAL TABLOIDS.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, E.C.)

EVER endeavouring to keep pace with the requirements of medicine as it advances, Messrs. Burroughs, Wellcome, and Co. have recently added some new useful tabloids to their already well-stocked list, specimens of which we have lately examined. The bismuth salicylate tabloid contains 5 grains of the bismuth salt, guaranteed physiologically pure, the dose ranging from one to four tabloids, which is equivalent to from 5 to 20 grains. Their convenience is evident, since bismuth salicylate is insoluble in water or spirit. This drug has been used with benefit (which may be referred to its astringent and anti-fermentative properties) in various forms of diarrhoea due to typhoid fever and pulmonary and intestinal tuberculosis. Easton's syrup tabloids, each equal to one fluid drachm of the syrup, will be accepted at once as a very convenient form in which to administer this excellent tonic. Lastly, the value and convenience of the tabloids of pepsin, bismuth, and charcoal will be obvious to every practitioner. We have submitted all the foregoing tabloids to qualitative analysis, with the result that evidence was obtained in every case that the drugs indicated were contained in them.

BREAD MADE FROM GERM MALT FLOUR.

(W. MARSHALL AND SONS, VICTORIA AND HAVEN MILLS, GREAT GRIMSBY, AND 39, HAMFRITH-ROAD, STRATFORD, ESSEX.)

This is an excellent specimen of malted bread made with the wheat germ, by the use of both of which not only is the proportion of food constituents very materially increased, but they are rendered also all the more digestible. It possesses a pleasant, though somewhat sweet, nutty flavour, and has the distinctly advantageous quality of keeping moist for a reasonable time. Its excellent dietetic properties are well brought out in the following analysis: moisture, 48.00 per cent.; albuminoids, 9.34 per cent.; mineral matter, 1.16 per cent. (of which 1 per cent. is soluble); soluble matters, 10.44 per cent.; unaltered starch, 31.06 per cent. Thus no less than one-fifth part of the solid matter is soluble in water, and is found to contain a valuable quantity of phosphates, while over one-sixth consists of nitrogenous (so-called flesh-forming) substances. A comparison of this bread with ordinary household bread shows at once its superiority in regard to nutritive and digestive value. The biscuits and cake also submitted are made on similar lines. We observe with considerable satisfaction the attention which is now almost universally being bestowed upon the improvement of the commonest, yet most important, article of our daily food. The above specimen, amongst others we have previously reported, fully justifies this remark.

OLD SCOTCH WHISKIES (NOS. 1 AND 2).

(STODDART AND CO., 20, SUFFOLK-STREET, PAUL MALL, S.W.)

Two specimens of whisky submitted by the above firm were characterised by a low proportion of extractives and a comparative freedom from acidity. Analysis gave the following results. No. 1: alcohol by weight 35.00 per cent., by volume 41.84 per cent., being equal to proof spirit 73.33 per cent.; acidity reckoned as acetic acid, 0.004 per cent.; extractives, 0.13 per cent.; ash, 0.04 per cent. No. 2: alcohol by weight 42.00 per cent., by volume 49.50 per cent., being equal to proof spirit, 86.75 per cent.; acidity reckoned as acetic acid, 0.006 per cent.; extractives, 0.130 per cent.; ash, 0.04 per cent. No. 2 is, therefore, superior in regard to its spirit contents; but No. 1 is the maturer specimen (twelve

years), as No. 2 is stated to be seven years old. The impression that both samples convey to the palate is that they are moderately mellow, but both are evidently free from those by-products of whisky distillation which are said to be productive of physiologically bad effects, and which age successfully eliminates.

COCOANA.

(SCOTT AND SCOTT, 24, HIGH-STREET, BIRMINGHAM; AND WESTON, HUNT, AND CO., 34, SEKTHING-LANE, GREAT TOWER-STREET, LONDON, E.C.)

The addition of banana flour to cocoa doubtless improves its digestible character, while it detracts nothing from its agreeable flavour. Cocoaana is compounded on these lines, as is evident from a microscopical examination. We regard this introduction as of some dietetic importance, since it further reduces the proportion of indigestible cocoa fat, while it does not overburden the cocoa with starches that tax the digestive functions.

"EVER-FRESH" BAKING POWDER.

(W. A. DANIEL, 18 AND 20, PARK-LANE, LIVERPOOL.)

The question of the legality of adding alum to baking powder was adversely decided by a recent case, when the Court of Appeal ruled that baking powder, not being an article of food within the meaning of the statute, might have all sorts of objectionable things added to it. This ruling prompted us some time ago¹ to publish the names of makers of powders free from alum, for the guidance of our readers. To this list must now be added the name of the maker of the above specimen, which we found to consist of perfectly pure ingredients. It evolves a desirable amount of carbonic acid gas on moistening, and keeps well, being packed in tight tins provided with lever lids.

(1) CHICKEN JELLY. (2) MUTTON JELLY. (3) CURRIED FOWL. (4) CURRY SAUCE.

(HALFORD, 12, UPPER ST. MARTIN'S-LANE, W.C.)

The value of meat jellies in impaired digestive function is well known, but, amongst other things, it is essential that they should possess a flavour which is acceptable to the fastidious palate of the invalid. It is especially from this standpoint that we regard the mutton and chicken jellies of the above manufacturer as a real success, the flavour of which, while being agreeably delicate, is still distinctive of the meat bases employed. Analyses gave the following results. Chicken jelly: moisture, 80.74 per cent.; mineral matter, 1.33 per cent. (chiefly potassium phosphate); meat extractives, 17.93 per cent. (of which 16.38 per cent. was nitrogenous matter). Mutton jelly: moisture, 85.38 per cent.; mineral matter, 1.51 per cent. (potassium phosphate); meat extractives, 13.11 per cent. (of which 12.78 per cent. consisted of albuminoid substances). They are both clear amber-coloured jellies, free from salt and burnt flavour, and will prove to be convenient restorative and stimulant agents for invalid use.

We have received, also from the same maker, two specimens of his tinned curried provisions—viz., curried fowl and curry sauce—for the excellence of which he has enjoyed a long reputation. They are free from reproach, so far as analysis goes, being evidently made from carefully selected materials, while they possess a delicate piquancy characteristic of the Indian-made dish. For export and for travelling purposes they supply a much felt want.

FACSIMILE HUMAN MILK.

(WELFORD AND SONS, LIMITED, BELGIN-AVENUE, MAIDA VALE, W.)

Although we cannot admit that the composition of this milk is literally a facsimile of human milk, still it approaches more nearly to mother's than it does to cow's milk. Our analysis was as follows: total solids, 13.08 per cent., containing fat 3.30 per cent.; mineral matters, 0.52 per cent.; specific gravity, 1032. It certainly possesses one very dis-

tinct advantage, which is that, being supplied from farms near London, the milk is dealt with when quite fresh, so that contamination and delay during transport are avoided. The specimen submitted to us was a pure and healthy product.

BURNHAM'S CLAM BOUILLON.

(SOLD BY GORDON AND DILWORTH, ST. GEORGE'S HOUSE, EAST-CHEAP, E.C., AND BURROUGHS, WELLCOME, AND CO., SNOW-HILL-BUILDINGS, E.C.)

The clam is, of course, a bivalve not found on English shores, but the above broth, we imagine, gives a very good idea of what its taste is like. The bouillon is a murky, opalescent liquid of saline taste, but possessing an agreeable, delicate flavour, calling very much to mind that of lobster. The following is an analysis of the sample submitted to us: total solid matter, 13.48 per cent.; organic matter, 9.12 per cent., containing 2.52 parts proteid matter; mineral matter, 4.36 per cent., of which 3.64 per cent. proved to be common salt. It will thus be seen that it contains a somewhat higher proportion of proteids which are soluble and uncoagulable by heat than does milk. The mineral matter consists largely, of course, of common salt, but phosphates occur in it as well. There is little doubt, therefore, that clam juice possesses distinct nourishing properties. We could trace no objectionable preservatives in the bouillon, or any evidence of metallic impurity, and we are glad to find that the makers recognise the desirability, or rather the necessity, of storing the broth in glass bottles in preference to metal tins.

GINGER BEER.

(HAY, REGENT'S-TERRACE, ANLBY-ROAD, HULL.)

In this well-brewed product the essence of ginger which is prepared by the above maker has been substituted for the ordinary hot-water decoction of the root. The advantage thereby gained is distinct as regards the palate, while, of course, the superfluous and useless extractives of the root which are opposed to the healthy condition of the beer are excluded. On analysis the following results were obtained: absolute alcohol by weight 0.79 per cent., by volume 0.99 per cent., being equal to proof spirit 1.74 per cent.; extractives, 11.26 per cent.; ash, 0.09 per cent. It is a pleasant beverage and free from the pungent principles of ginger substitutes, which are not infrequently met with in preparations of this kind.

AUSONIA NATURAL ITALIAN MINERAL WATER.

(COSENZA AND CO., 95 AND 97, WIGMORE-STREET, CAVENDISH-SQUARE, W.)

This table water possesses pronounced alkaline properties, and is only slightly charged with carbonic acid gas, being bottled in the same condition as it flows from the spring. It is markedly soft to the palate and yields on evaporation 95.20 grains of saline matters per gallon, composed chiefly of alkaline carbonates, with but a trifling quantity of common salt. Like most waters of its class, it possesses distinct diuretic properties, and is further claimed to be an aid to digestion—simply, we infer, on account of its acid neutralising qualities.

New Inventions.

THE NARCOTISING GLASS MASK.

DR. WILLIAM VAJNA of Budapest has invented a simple and clean inhaler for the administration of anaesthetics. The inhaler, which we figure below (Fig. 1 and 2), consists of a cut-glass mask shaped so as to cover the mouth and nose. It is held in position by a glass handle which is easily grasped by the finger and thumb or two fingers. The edge of the glass is carefully trimmed, and is supplied with an indiarubber band, while the upper part of the mask has flannel stretched across it, just as a drumhead is fitted. The chloroform or whatever anaesthetic is to be employed is dropped on to this flannel. The following advantages are claimed for this mask: 1. It is easily and rapidly

¹ THE LANCET Special Analytical Sanitary Commission on Yeast Substitutes, with especial reference to the use of Alum in Baking Powders. THE LANCET, March 3rd, 1894.

cleaned, the flannel and indiarubber band are replaceable, while the glass can be boiled and sterilised with disinfectants. 2. The transparency of the mask permits of the patient's face being watched throughout the administration. 3. The anæsthetic cannot trickle down the glass, as

FIG. 1.

Vajna's mask. A, transparent glass mask; B, elastic band; C, flannel covering over top.

it is caught by the rim, and so cannot drop upon the patient's face or be wasted; this ensures economy. 4. It enables the administrator to carry out with accuracy the "drop method" of giving chloroform; Dr. Vajna believes in this method and advocates it in the case of persons

FIG. 2.

Mask held in situ.

in feeble health and for alcoholics. 5. In the event of vomiting or foul expectoration occurring during anæsthesia this mask, being so easily cleaned, possesses obvious advantages. Dr. Vajna has also provided a "rose"

FIG. 3.

"Rose" for evaporating the anæsthetic.

(Fig. 3), which is placed on the flannel inside the mask. Bromide of ethyl or nitro when used are dropped upon this "rose" and the mask kept closely applied, ten or

fifteen grammes being the quantity of bromethyl used. If more is needed it is added from the outside. For ether the mask is said also to answer well. The "rose" being placed in position (Fig. 4), ten or fifteen grammes of ether are

FIG. 4.

Mask fitted with (R) the "rose" in situ.

poured on it and the mask carefully fitted over the mouth and nose. More may be added as required from the outside. The ether flows to the lower surface of the "rose," where it is held by capillary attraction and evaporates close to the patient's mouth. If the interior of the mask grows moist it can be wiped or the inconvenience obviated by smearing the glass with a thin film of glycerine dissolved in water. The inventor claims for this mask that it answers well for any of the anæsthetics mentioned above, and thinks it superior to most of the appliances used in the Continental hospitals. In the case of chloroform and its congeners we have found it admirably adapted for the purpose for which it is devised. In operations about the face and neck, in which it is necessary to avoid the possibility of septic infection, Dr. Vajna's mask is most valuable. Whether it can be used as successfully for the induction of narcosis by ether must, we think, be assumed with less confidence.

"RELIANCE" CLINICAL THERMOMETERS.

THE accompanying diagram illustrates a new shape of clinical thermometer which has been the outcome of practical experiments made to satisfy the requirements suggested by the authorities of St. Bartholomew's Hospital, they being desirous of having a clinical thermometer provided which would be much stronger in the constricted portion and so obviate the expense of having to replace numerous breakages. Messrs. Arnold and Sons have succeeded in making a clinical thermometer whereby the constriction is the strongest part of the instrument, so that if dropped on the floor it would certainly not break at that part of the stem. In all other ways the new form will be found to be as good as the ordinary pattern, taking a record of temperature with equal rapidity. This seems to be one of those new ideas which ought to have occurred a great deal earlier to a great many people; it is so simple and yet meets so well-known an annoyance. What sum annually is lost to our hospitals in London alone by the breakage of clinical thermometers would make an interesting calculation—the total would certainly be equivalent to a sum sufficient to support two beds, and a large proportion of these fractures take place at the constricted waist. Children also are apt to fit their teeth into the groove, with disastrous results.

THE LANCET.

LONDON: SATURDAY, JANUARY 5, 1895.

It has long been our custom when standing upon the threshold of a new year to pass in review the leading facts which affect the position of THE LANCET in its relations to the Medical Profession. Those relations are, indeed, of such a character as to demand from us from time to time an account of our stewardship. For it is our aim to make THE LANCET in the fullest sense the organ of professional opinion and the just reflection of professional sentiment—not of any mere section, however large, or of any clique, however influential; and to our readers, therefore, we incur a double responsibility. Not only do we propose to ourselves to furnish them from week to week with information and news, but also to utter and record their own feelings upon the various matters which come successively into prominence, and thus to fulfil at once the functions of eyes and ears and speaking-mouth to our constituents. The fulfilment of such an office implies the closest communication between our readers and ourselves.

There is one branch of our work to which this year we desire and intend to devote especial attention—namely, the Mirror of Hospital Practice. The brilliant results which have in recent years been reached in the direction of biological study—particularly of pathology and bacteriology—have tended perhaps to throw somewhat into the shade in what may be called “public estimation” the painstaking labours by the bedside. But those who are actually engaged in the practice of the healing art can never lose sight of the capital importance which attaches, even for purely scientific purposes, to clinical study. Comparisons are never so odious as when they are drawn between two excellent things for the purpose of disparaging one of them. We shall not, therefore, seek to determine the relative importance of research work and bedside observation; but it is perhaps not unfitting to point out here that the work of clinical observation and record is one which makes well-nigh as great a demand upon the time of the observer and upon the space devoted to the record of observations as do the achievements of the laboratory. For this reason such work has a peculiar interest for us to-day, when the rôle of medical journalism in promoting the science and the art of medicine is specially under notice. In the Mirror of Hospital Practice may be found a vast collection of what may be termed medical or surgical achievements, always significant, although removed by their rarity from the opportunity of frequent observation. But what the clinical record must necessarily, from the nature of the facts to be recorded, want in precision is to a large extent supplied by the variety of its instances; while every observation made under those conditions has the advantage of being an exact case in point, so far as its goes. Nor is this all. We make use of the material by quoting parallel cases and giving full references to similar procedures, with bibliography when it is available. Man is to the medical practitioner by far the most interesting

of all possible object of observation and he never feels quite so sure of his ground as when he is building upon this foundation.

Another branch of our work in which the coöperation of our professional brethren bears a principal, though somewhat less formal, part comes naturally to mind at the present moment, when we are awaiting the detailed reports of the Indian Medical Congress, which has recently concluded its sittings at Calcutta. In the reporting of such proceedings there is of necessity a considerable exercise of editorial discretion in the making of necessary abridgments and the choice of opportunities in the way of deciding upon the early publication of a cursory notice or the delayed publication of a full report. It will easily be credited that the exercise of this discretion is at times not at all an easy task, for it may happen that the importance of an original communication is by no means recognised, perhaps by no means recognisable, at the time when it is first made. For example, the earliest notice which THE LANCET contained—and, for that matter, any English journal contained—of the antitoxin treatment of diphtheria was comprised in a very brief notice of a communication on the subject made to us by our special correspondent at Berlin, and serves to show in a very striking way how the routine of publication secures a measure of recognition and an effective publicity for all matters of abiding interest, even although their full significance may not be recognised at the time when they are, so to speak, automatically placed on record. If, on the other hand, it were necessary to draw attention to the admitted importance of many of the addresses which have been reported *verbatim*, and with a minimum of editorial preparation, in our pages it would be easy to draw from the year just closed many striking illustrations. Thus far we have spoken of what has long been an established routine, but the problems which face the medical practitioner of to-day cannot be solved by the use of any universal formula or, indeed, by any number of familiar methods of solution. The growth of science, the spread of civilisation, changes, some for the better, others for the worse, in modes of life; all these things are constantly preparing new problems, new difficulties, new duties for the medical man. The introduction of steam at the beginning of the present century revolutionised the conditions of life, affecting all classes of society in turn and none more profoundly than the medical profession. The introduction of electricity into the arts bids fair at the end of the century to repeat the marvel. To keep the pace new appliances must be brought into use and new energy be constantly infused. Our readers are aware that some two years ago we found it desirable to establish an Analytical Laboratory under editorial supervision, and the evidences of its activity have been continually before our readers in a succession of reports. The important commission upon the Hermite process of sewage treatment—to which we made allusion in our notice of the past year last week—will be within the recollection of most of our readers. That even in this department of our work we depend upon the coöperation of our readers may be illustrated by the inquiry into the value of coffee extracts as anti-narcotics in opiate poisoning. This inquiry was suggested by a discussion which arose in our columns as to the value for this

purpose of the coffee extracts of commerce, and resulted in establishing the very satisfactory conclusion that, although the proportion of caffeine varied within considerable limits in various samples subjected to analysis, this agent was present in effective measure in all articles sold under this description.

Of the more strictly editorial branch of our work it does not become us to speak in detail, but we need not hesitate to repeat, as we have said before upon occasions like the present that it is the knowledge that we possess the confidence of our professional brethren which gives us courage to face the duties of a new year. We are by no means insensible to the responsibilities of the position which it has always been our endeavour and our ambition to fill. We have abundant reason to be aware of the labour and difficulty which it involves. But so long as we receive from the profession a continuance of the support which has been for nearly seventy-two years generously extended to THE LANCET we shall take that to be our sufficient warrant for believing that we have not failed to justify in some measure the claims which we have put forward, or to serve according to our power the generation in which our lot has been cast and our fellow labourers in the great field of medicine.

THE general interest awakened by the introduction of a method of treating diphtheria, which has at least the merit of being based on strictly scientific deductions, illustrates the prevailing familiarity with the disease in the present day and the appreciation of its dangers. Diphtheria occupies, in truth, a notable position amongst the zymotic diseases, and the fact that it shows a tendency to increase its ravages, in spite of advances in sanitation, makes it all the more necessary that the means of combating it should be extended. It has of late years received abundant attention on all hands, but the conditions of its origin have yet to be accurately defined. Thanks to the labours of many epidemiologists, there is much material gathered to frame its history on the large scale, to prove its infectivity, and to suggest the adoption of means to prevent its spread. But there are many lacunae to be filled, as, for instance, its relationship to allied affections of the throat, its possible connexion with animal diseases, its precise association with insanitary conditions of the "pythogenic" class, together with the problems that arise in respect to outbreaks in small communities in rural districts as compared with those arising in densely populated towns. These are questions of high importance; but they concern rather measures of prevention than those of cure. For the latter we must look—as alone we should ever look if medicine is to have a scientific basis—first to the pathological facts that have been slowly garnered concerning the disease. For if we can confidently affirm that we know its nature there is room to hope that means will be found to combat it. And it is mainly because this sero-therapeutic departure claims to be founded on the true conception of the nature of diphtheria that it has been received with so much confidence.

The history of the growth of pathological doctrine regarding diphtheria—in other words, the gradual building up of

a rational explanation of its nature—is one of the most interesting examples of the evolution of ideas that medicine can offer. In the early days of this study diphtheria was regarded, it is true, as a specific disease, but it was ranked with fevers as being primarily a "constitutional" affection, having as its especial local manifestation the membranous inflammation of pharyngeal and laryngeal mucous membrane. It was pointed out that the "membrane" re-formed if it were stripped off, and that any raw surface in a diphtherial patient might become coated by this deposit. The peculiar character and extent of this inflammation were studied and the contrast with "croup" emphasised, so that the terms "croupous" and "diphtheritic" came to be applied to inflammatory conditions of mucous surfaces quite independently of the disease diphtheria, standing merely as pathological terms. We need not here reopen the question, so long and ardently discussed, as to the relationship of croup and diphtheria, but we can only express regret that the terms were introduced into pathology as they were. That the disease diphtheria was one which affected the whole organism was evidenced by its concomitant fever, albuminuria, and the sequential paralysis; but that there were special dangers attending the local inflammation, and in particular from its extension to the air passages, was recognised in treatment long before the alternative conception of its nature was adopted. Thus, side by side with general tonic and restorative remedies, local applications, some of great severity, were made to the throat to arrest if possible that spreading of the inflammatory exudation which was so grave a source of danger. Gradually, however, the alternative and truer idea of the disease arose, and was found to be in harmony with the facts, clinical and pathological, which had accumulated on all sides. This was the view that the throat affection which marked the onset of the disease merely indicated the place at which the virus entered the system. Many years ago the possible source of this virus being fungoid arose; but it was long before any conclusive proofs could be adduced of the real nature of the parasite concerned. Even before the bacillus identified by KLEBS and by LÖFFLER had been admitted as the specific agent minute and careful histological research had shown that the tissue changes in various parts and organs of the body were identical with those present in the submucous layers of the inflamed pharynx; and the hypothesis of a virus formed at the seat of entrance and absorbed thence into the blood was adopted long before bacterial toxins were thought of. The rationale of prompt and early local treatment was thereby established, whilst internal medication and supporting measures were justified as aiming to sustain the organism under the depressing influence of the general intoxication. When, finally, it became clear that the specific microbe could be identified and isolated, and that its metabolic products could reproduce in animals the essential lesions that characterise the human disease, the finishing touch was put to the juster comprehension of its nature. But bacteriology has not stopped here; it has shown that the diphtherial exudate contains other organisms besides the specific bacillus, and we have yet much to learn concerning the part they play in the various manifestations of diphtheria. That they are not essential

to the production of its main phenomena—e.g., the cardiac failure, the albuminuria, and the later-*arising* paralysis—seems clear; but they may, and probably are, responsible for modifying the character of the local inflammation and for the development of septicæmic symptoms, which sometimes complicate the disease. The supervention of laryngeal obstruction has no specific character; it is merely a mechanical effect, due to the accident of the bacillary invasion of the respiratory passage, either in direct extension from the naso-pharynx or independently of any implication of the latter.

It is hardly necessary to dwell on the grounds upon which the new "serum therapeutics" are based. They are so recent and so fresh in memory as to need no recapitulation. Suffice it to point out that the method is strictly in accordance with the prevalent acceptance of the nature of diphtheria and with the facts concerning the antagonism to bacterial poisons that have been established by laboratory research. If the results hitherto obtained are confirmed by extended trials the gain to our power over disease will indeed be great. We may look for even more brilliant results if there be no flaw in the chain of reasoning which has led to the advocacy of the method. For should this be correct, we have in these "antitoxins" the *specific* remedies which have been desired since medicine emerged from pure empiricism. The present methods may be crude, and we may look forward hopefully to a time when they will be more refined; but unless the whole fabric of bacteriology is unsubstantial and visionary there is reason to believe that a path has been opened in treatment which may lead to our mastery over those acute infective diseases whose virulence has wrought more havoc on the human race than can well be estimated.

The time has arrived when the method will be tried on a large scale in this country. That it is not an easy question to determine must be obvious to all. It involves, amongst others, questions of diagnosis, of dosage, of effects due to the remedy *per se*, and of the right estimation of its results as regards the natural course and termination of the disease. An inquiry, to be thorough, must enter as fully as may be into the clinical and pathological history of diphtheria, not only during the period in which the method is being applied, but over a sufficiently long period prior to this. Of the method of study of its effects in individual cases the admirable paper brought before the Clinical Society of London by Drs. WASHBOURN and GOODALL and Mr. CARD¹ offers a good example. Considering the importance of the matter at issue, we can well afford to wait for months, or even years, for a definitive decision on this question. We are not singular in this opinion. It has been expressed by men of authority elsewhere, who have deprecated hasty conclusions both for and against the new treatment, which in this impatient age men are so apt to form.

THE movement in favour of hospitals for poor phthisical patients has made some progress during recent years in this country, and also in Scotland and Ireland. The nation is, however, still far from having grappled courageously or suc-

cessfully with the very difficult questions which arise in this connexion, and which press urgently for solution. When we reflect upon the fact that about one person out of every seven who die succumbs to phthisis, and think of the hundreds of thousands of phthisical patients who must exist in these islands, and of the paltry number of beds available in the different hospitals for the treatment of the disease, we feel that the machinery of charity breaks down hopelessly at one of the most vulnerable points of the body politic. Yet it would be foolish to ignore the palpable fact that hospitals for the treatment of phthisis stand on a very different footing from hospitals devoted to the treatment of disease in general, or to deny that the limited support which they have hitherto obtained is, if not defensible, at least quite intelligible. To begin with, the disease is popularly regarded as incurable, and there is a widespread feeling that money spent in organising hospitals for its treatment brings no adequate return. Then the treatment of phthisical patients, if pursued according to modern ideas, is more than usually expensive, owing to the generous dietary which is a *sine quâ non*, and many people, sufficiently well-disposed, prefer to give their charitable contributions to objects where economical management is more practicable than it is in the direction of hospitals for phthisis. The frequency of relapses in patients discharged from such hospitals is another explanation of the not uncommon prejudice against them. It is, moreover, open to question whether hospital treatment is of much avail in arresting the progress of the disease where climatic conditions are unsuitable; but, compared to the homes they come from, the phthisical poor gain the benefit of attention and comfort. We think it important to inquire what may be fairly expected from such hospitals, and what views regarding them should be impressed by the medical profession upon the charitable public.

First, we think we are quite justified in asserting that in a certain, perhaps small, proportion of cases of phthisis complete recovery may be fairly expected under favourable conditions. Pathological and clinical evidence both favour this view, but, on the other hand, in any given case of developed phthisis the prognosis must be admitted to be bad. Without unduly pressing the evidence in favour of the more hopeful view of this subject, we have ample ground for the assertion that a certain proportion of properly selected incipient cases will be cured by the carefully regulated hygiene and treatment carried out in a hospital for the treatment of the disease. This is the crucial point on which a large amount of difference of opinion will be found to exist both within the ranks of the medical profession and among educated laymen. Without attempting to argue this question in any adequate manner, we may remind those who dissent from the view above enunciated that it is quite common to find evidence of old-standing and obsolescent tuberculous disease of the apex in patients dying as the result of accident or acute affections. On the clinical side, every physician sees numerous cases of patients who had hæmoptysis and were believed to be "in consumption" in youth, but who, nevertheless, completely regained their health. This, then, should be the first line of defence on behalf of these institutions—viz., that as a matter of fact they do effect some permanent cures. In the second place, we may fairly say that there

¹ THE LANCET, Dec. 22nd, 1894.

are many cases of well-developed but quiescent phthisis where complete recovery is, indeed, impossible, but where some weeks or months of careful treatment in a suitable institution may enable the patient to return to his family and his occupation and for a time discharge the duties of a useful member of society. Such cases are not rare, and no one with much special experience in this department will question their existence. Let it be granted that in such cases relapse is the rule and that the period of useful work is generally short, yet in so discouraging a disease we must for the present be content with small results in treatment. It would be bad philosophy to throw away these small results through impatience or discouragement.

Lastly, hospitals for phthisis have a work to do in connexion with obviously hopeless cases. There are none of the numerous complications of advanced phthisis which do not admit of some palliation and relief, and when we think of what these poor patients suffer in their small, ill-ventilated, and uncomfortable homes our appreciation of even the least hopeful phase of the work of these hospitals will probably rise. It is, however, a very serious question whether advanced and moribund cases should be treated in the same institutions as incipient and hopeful cases. Such a conjunction of cases is beset with many disadvantages, and it may be in the probably distant future that hospitals for the treatment of the malady will be confined to incipient cases, and that advanced cases will be relegated to hospitals for incurables.

An argument for the existence of these hospitals that is likely to gather weight as years go on is the necessity for such institutions in order to segregate the patients and prevent the spread of disease by contagion. Here, again, it is most important not to strain the facts or to overstate what is a sufficiently strong case. We think there is evidence for regarding phthisis as a contagious disease, but it is evident that it is only very feebly contagious, and only contagious under special and exceptional conditions. Beyond this we do not feel it possible to go at present, but, even taking this very moderate view, we can find in it substantial ground for strengthening the argument for the existence of hospitals for phthisical patients. The experience at present being gained in Great Britain, on the Continent, and in America regarding the best methods of conducting such institutions is sufficient to afford valuable guidance for the future. These hospitals should, when practicable, be in the country and surrounded by ample grounds. The sites should preferably be either on elevated ground or adjoining the sea or among pine forests. The soil should be dry and porous. There should be ample access of sunlight and adequate shelter from cold winds. Sheltered level walks are very desirable.

In this age of associations it is not surprising that we find a proposal made for the formation of an "Association of Qualified Assistants, Junior Medical Officers, and Locum Tenens." The number of gentlemen comprehended in one or other of these three classes must be considerable, and their interests need to be vindicated like those of any other body of men in a somewhat weak position—weak, firstly,

in the sense of being in an essentially subordinate position, and, secondly, in being isolated and unorganised. The more the employment of unqualified assistants is decried and discouraged the more does the position of the qualified assistant rise in dignity and importance, and the more natural is it that these gentlemen should have some common bond of sympathy and, if need be, some machinery for combined action. The action of the General Medical Council in disapproval of the employment of unqualified assistants in any responsible capacity has tended much to quicken interest in this subject on the part of both principals and qualified assistants. We shall therefore look with interest to the response to our correspondent's letter proposing the formation of an association of qualified assistants. The proposal is not one to be rashly disposed of. It is a subject which should be fully discussed and all the objections to it, as well as the arguments for it, should be fairly stated. Principals need not see in such a proposal anything unfriendly to them. All other means for acquainting them with the views of the General Medical Council on the subject of unqualified assistants have been only very partially successful. There is reason to believe that in many districts this is still the rule. And year after year practitioners have to be removed from the Register who avow that they have never heard or seen anything of the limitations imposed by the Council on the use of unqualified assistants. One effect of an association such as that proposed would be to give accurate information on the subject and on the extent to which the limitations of the Council are observed. It would be an error to promote such an association in any hostile spirit, save in hostility to practice by unqualified persons. The demand is more and more that all attendance shall be by, or under the immediate superintendence of, registered practitioners. It would seem that with the solitary exception of the employment of students in their fifth year of education as pupils of a practitioner recognised by the examining authorities and under his supervision, all unqualified assistance is discouraged by the General Medical Council. Medical principals must therefore conform to this. If it involves more expense on their part they must recoup themselves. The public is to be protected, and the public must pay for the protection and for the better service it involves. We have said enough to show that there is some reason in this proposal; but we are not blind to the difficulties of carrying it out or of creating an association that would deal effectively with the evils which it is designed to meet. Qualified assistants have little time and not much money to promote such a big reform as that contemplated or to bring individual cases before the General Medical Council; but they can contribute their share to the general elucidation of a subject which is now very much to the front, and in any moderate and judicious proposals they would have the concurrence of their principals and of many other principals besides.

THE British Medical Benevolent Fund has received a legacy of £500 under the will of the late Mr. F. M. Stone.

Annotations.

"Ne quid nimis."

THE NEW YEAR'S HONOURS TO THE PROFESSION.

GENERAL satisfaction has been felt throughout the medical profession at the announcement that the Queen has been graciously pleased to create two new medical baronetcies and to select for the honour Dr. J. Russell Reynolds, the President of the Royal College of Physicians of London, and Mr. Erichsen, a past President of the Royal College of Surgeons of England. Names, from an official point of view, more representative of the two great divisions of the healing art could not have been well suggested, and personalities more eminently fitted to worthily grace the honours cannot be well imagined. It is not our intention here to recapitulate the claims either of Sir John Russell Reynolds or Sir John Eric Erichsen to the Royal recognition which they have just received; we only desire to echo what we know is the sentiment of the profession at large by assuring them that Lord Rosebery's recommendation would have been the recommendation of all their professional brethren, and that we are glad to know this fact and to record it. One small reflection occurs to us, and, as medical journalists in an age prolific of writing, we think it will not be out of place to make it. Both the new baronets are men of singular literary capacity. To the lucidity of Erichsen's comprehensive and closely written work on surgery generations of students have owed their theoretical knowledge of their science; while Reynolds's *System of Medicine* was at its issue acclaimed in our columns and universally the standard English text-book of medicine.

"THE STRUGGLE FOR THE LIFE OF OTHERS."

DR. CHRISTOPHER MARTIN recently delivered an interesting address under this title at Birmingham before the Queen's College Medical Society. All who have impartially studied the question are now agreed, he said, that man, in common with the lower animals and with plants, has undergone development in accordance with the laws of evolution. In this developmental process two great influences have been at work: (1) the struggle of each organism for its own life, and (2) its struggle for the life of others. The first of these was recognised by Darwin, Wallace, and Spencer, who formulated the law of natural selection by the survival of the fittest in the struggle for existence. They saw the dark and selfish side of creation and nature's disregard of suffering. But Professor Drummond, in a recent work,¹ has pointed out that from the beginning another and a holier influence has also been in operation—"the struggle for the life of others." In many instances it might be termed "labour for the life of others," the spirit of love in nature. The two fundamental processes of life are nutrition and reproduction. The selfish struggle for existence arose out of the necessity of fighting for food, and is, therefore, directly related to the function of nutrition. The unselfish struggle for the life of others arose out of the necessity for perpetuating the species; it is, therefore, the resultant of the function of reproduction. Throughout all animated nature the process of reproduction involves more or less self-sacrifice on the part of the parent organism. In some of the primitive annelida the mature female dies in liberating the ova. Among the birds the hen laboriously warms her eggs with the heat of her body until the chick comes forth, while the male defends his home from attack and gathers food for his young. These feathered parents do not cease their ministrations till their progeny have

learned to fly and forage for themselves. What a tremendous power this struggle for others has exerted in raising mankind out of the beast. According to Professor Drummond the chief factor in this supreme achievement has been the evolution of the unselfish mother. When savage man lived wild in the woods as the ape does now, suppose that two mothers—one selfish and the other unselfish, each with her helpless offspring—were attacked by some common foe; the former flies and abandons her young; the other, who has learned to love her offspring, stays to fight for its precious life or carries it off to a place of safety. The child of the selfish mother perishes, whilst that of the unselfish one survives. The good qualities of the nobler parent are inherited by the surviving child, and so the spirit of self-sacrifice grows from generation to generation. Compared with the mother the father plays but a secondary part in the struggle for others. The dawn of the paternal instinct appears in fishes, in many species of which the male prepares a retreat or nest for his mate to spawn in and assists her in guarding the ova. Among many species of birds a kind of temporary family life is established during the breeding season, and the male takes part in the duty of rearing the young. Among the mammals there is no trace of family life until the human savage is reached. The males of the subordinate mammalian genera fight for their own life and sustenance and for the satisfaction of their animal desires, but they do nothing on behalf of their progeny. According to Westermarck it is the abolition of the physiological pairing season which has effected this change in the case of the human being. This led to the formation of permanent instead of transient love relationships between man and woman, and, family life having been thus established, the foundations of civilisation were laid. Out of the family rose the tribe, and out of the tribe the nation.

THE HEALTH OF FLORENCE.

WHETHER the Florentines are or are not justified in their confident expectation that the Queen of England will, after her *villeggiatura* in Nice, spend the remainder of the spring in their own beautiful city, we may at least congratulate them on the improved sanitation they have been instituting in that belief. Exceptionally free from zymotic disease as Florence was last winter and spring, her record is even more reassuring for the season now passing. True, the prolonged *tramontana* has levied its tribute on the aged and infirm, and the deaths of prominent citizens among the native and foreign population have once more attested the rapidly fatal course acute pneumonia may run. But excluding that source of disease and death as common to most southern cities at the transition from autumn to winter, we can find as yet in the health returns of Florence nothing but clear and cogent proof that the low mortality of the past year has been more than maintained. A death-rate of from 17 to 18 per 1000, and that, moreover, during months when infectious disease is most diffused and most virulent, is what very few continental cities can boast. The fact, indeed, is one among many which explains the popularity of the Tuscan capital as a winter city for the English-speaking resident. Florence can point to a greater number of such inhabitants than any European centre south of the Alps—indeed, in proportion to native population, she has a more numerous contingent of English-speaking "strangers within her gates" than any other of her continental sisters. Her natural, historical, and artistic attractions, above all, the charm she possesses as Italy's "Modern Athens," might explain her having as large a migratory population as Rome, for example. But only her salubrity, over and above those attractions, accounts for her superior Anglo-American population, whose residence within her urban and suburban bounds extends not to a few weeks,

¹ The Ascent of Man.

but to many months, and that year by year. Fully alive to the advantages she secures by the presence of such a society, she is at pains to uphold the sanitary conditions under which it remains and multiplies. A *communiqué* from her hygienic bureau within the last few days of 1894 has, from this point of view, a significance of its own. "Except the month of January"—so runs the communication—"which owed its slight increase of mortality to a brief and transient visitation of influenza, all the rest of the year now closing showed, if anything, a diminution in the death-rate as compared with the year preceding, which, as regards the public health, was in all respects excellent. The later months of 1894 have registered a marked decrease in the fatal cases usual at that season; while not less notable has been the diminution throughout the whole year in the death-rate specially due to infective maladies. These, in fact, have touched a figure so low as to have fallen short of all expectation or forecast." An inspection of the monthly bulletins issued by the communal board of health will be found to confirm this reassuring statement, and we have only to add our congratulations on the result, and expression of the hope that the sanitary efficiency which explains it will continue unimpaired, even if Florence is, after all, disappointed in her expectation of once more welcoming Queen Victoria as her guest.

DIPHTHERIA IN LONDON.

DIPHTHERIA in London has in the last two weeks shown a disposition to decline both in amount of attack and in severity of type. In the four weeks of November the number of notifications in London was 911; but in the same period in December the notifications fell to some 780. The deaths, however, were not very different in the aggregate in the two periods—namely, 188 and 181; but in the last four weeks a large decline has been witnessed, the numbers having been 57, 53, 36, and last week 35, or 20 per cent. of notified cases. The 71 deaths of the last fortnight of December included 4 in Lambeth, 5 in Battersea, 7 in Greenwich, and 6 in Islington sanitary areas. Of the total, 43 were in children aged from one to five years, and other 23 in young persons under twenty years of age. The deaths of last week were just equal to the 'corrected average. The admissions to hospitals of the Metropolitan Asylums Board were 75, against 104, 111, and 80 in the three weeks preceding; and similarly the patients remaining under treatment last Saturday were 521, against 514, 521, and 510. In Greater London there were 15 deaths from diphtheria in West Ham alone during the latter half of December.

CHARITABLE DONATIONS IN 1894.

ACCORDING to the *Charity Record*, the charitable bequests made during the past year have not been as numerous or large as in 1893. Nevertheless, it is estimated that, for medical and other charities for giving actual relief, something like £3,000,000 has been subscribed or bequeathed during the year. This does not include, of course, what has been given for missionary and educational work. The sums devoted to these latter purposes are much larger, and the claims of education and of religious propaganda contribute undoubtedly to considerably decrease the amount that would otherwise be available for the relief of actual physical suffering. The greater part of the money bequeathed to other than religious and educational institutions has been left to hospital and convalescent homes. Thus, to take only the larger sums, Mr. Barbour, formerly M.P. for Paisley, has given £15,000 to build an infirmary for that town; Baron Hirsch has subscribed £15,000 to the London hospitals; the Earl of Leicester, by giving an additional

£5000 has brought his endowment of the Fletcher Convalescent Home of Norfolk up to £20,000; and Messrs. Heath have subscribed £20,000 to the North Staffordshire Working Men's Convalescent Home. Mr. Samuel Weston of Manchester has left to the charities of that town the munificent sum of £115,000. Of this legacy, the Royal Infirmary will get £50,000, and the Salford Dispensary, the Deaf and Dumb Schools, the Blind Asylum, St. Mary's Hospital, and the Convalescent Hospital will receive £10,000 each. Mr. John Clark gives the Paisley Infirmary and other institutions £28,000. Messrs. Schlizzi leave to London, Athens, Constantinople, and Island of Scio charities £20,000. The trustees of the David Lewis bequest offered £70,000 to some Manchester hospitals so that a maternity hospital might be built. Miss Rolleston left £20,000 to metropolitan charities, and Mr. Matthew Honan of Cork, £48,000 to the charities of that city. Mrs. Elizabeth Allan has bequeathed £60,000 to be distributed among the London hospitals, and Miss Wells has left £12,000 to the Lincoln Hospital. In concluding its long list of donors and benefactors, the *Charity Record* mentions the Metropolitan Hospital Sunday Fund, and estimates the amount obtained as £34,000. This is nearly £10,000 short of the sum actually collected; namely, £43,679.

THE RELATION BETWEEN STERILITY AND UTERINE FIBRO-MYOMATA.

THE influence of fibroid tumours of the uterus on conception, pregnancy, and the puerperal state has been recently considered by Hofmeier in a paper an analysis of which appeared in the *Annales de Gynécologie* towards the end of last year. The question as to whether there is any etiological relation between fibroid tumours of the uterus and sterility, either absolute or relative, is one of considerable interest. The current impression undoubtedly is that the relation between them is causal rather than accidental. As in the case of so many other accepted views, the accuracy of this one is now called in question, and a careful consideration of the statistical evidence adduced by Hofmeier makes it clear that, even if we cannot unreservedly accept his conclusions, there is at least sufficient ground for doubting the views hitherto commonly accepted as correct. Hofmeier's figures are based on a total of 213 cases of women with fibroid tumours of the uterus. A review of the details in this series of cases enables him to say that about 25 per cent. of women affected with uterine fibroids and seeking medical treatment are not married, 75 per cent. are married, and of these from 25 to 30 per cent. are sterile. Now, before drawing any conclusion from these figures, it is necessary to know what the percentage of sterility is among the whole class of married women. Probably further information is needed before we can state this exactly, but in the meantime, if we take the percentage of sterility among married women generally, as given by Matthews Duncan, at about 15 per cent., it will be seen that while there is a difference between this percentage and the percentage of sterility among married women affected with uterine fibroids, it is not so great as one might have expected. Still, at first sight—and we are not prepared to say at present that the conclusion is wrong—these figures would seem to justify the opinion that women with fibroids are about twice as likely to be sterile as other married women. Looking carefully into the matter it appears, however, that there is some reason to doubt whether the sterility should be ascribed to the presence of fibroids, or to some other cause. The duration of the sterility in each case, and the date of the first appearance of the symptoms of the fibroid tumours, are important points requiring consideration. Thus the average age of thirty-eight married sterile women was 41.4 years, and the duration of the sterility about sixteen

years. Here, if the sterility is to be put down to the presence of fibroid tumours, we should have to suppose that when the patients were about twenty-five years old the tumours were already exerting an influence unfavourable to conception; whereas, clinically, we know that uterine fibroids are not commonly met with till later in life. It is, however, conceivable that they might at an early period of their development, before giving rise to symptoms, and before attaining a size that would enable them to be recognised clinically, nevertheless have an effect in rendering conception less likely to occur. It should be mentioned that inquiry showed that in some of the thirty-eight cases referred to the patients had been under gynecological treatment ten or fifteen years before the fibroids appeared. We cannot follow the writer's thoughtful and suggestive paper further in detail, but we may just say that he considers that in most sterile women with fibroids the sterility must not be ascribed to the presence of the fibroids, but to some other cause, chiefly because the sterility almost always dates back to an age when in all probability there were no fibroids present. We have indicated a possible fallacy in this argument above. While the writer does not go so far as to say that fibroid tumours in themselves favour conception, yet in so far as their presence frequently prolongs the period of activity of the whole generative apparatus, and especially of that of the ovaries, they do in that sense increase the chance that pregnancy may occur.

SIR J. RUSSELL REYNOLDS ON THE MEDICAL STUDENT.

MAN changes, but changes slowly. If his "thoughts are widened by the process of the suns" they are only greatly altered where perception changes with increasing knowledge. The change in human nature is too small, since Socrates and Plato lived and saw and thought, to make that which they said less precious than any words that have been uttered in the centuries since they lived. Medical education has progressed with long strides during the last thirty years, but medical students are very much the same. Their tendencies to work or idleness are only altered as far as external forces have been organised to help the one and to repress the other, and any difference that can be discerned is small, and rather one of aspect than reality. As far as we are aware, the characteristics of the medical students who surround the bedside have been once, and once only, made the subject of a bedside lecture. It was not, indeed, given in a hospital ward, but in a theatre, yet its most appropriate title would be "A Clinical Lecture on Medical Students." Thirty-one years have passed since this lecture inaugurated a winter session at University College and was published in THE LANCET. We can do no greater service to the profession, to those who are or have been students, and we believe we can give them no greater pleasure, than by reproducing to-day the address which we printed on Oct. 3rd, 1863—reproducing it when all are recognising the justice of the honour bestowed upon the lecturer. And in going so far out of ordinary routine as to reproduce *verbatim* an address delivered as many as thirty-one years ago, we may be excused if we dwell a little forcibly upon our reasons. They lie in the words of the lecturer. Behind the graceful touch which sketches salient features with such accuracy can be discerned the strength of deep conviction, while confident precision is wedded to the apt use of phrases. Nor is this all. There is a deeper meaning which can escape no teacher and no one whose later experience throws into light or shade the memory of his student life. The types of student here portrayed are types of average aggregates, but the truth to nature of their features is conspicuous. They present the

lineaments known so well to every one who has had to observe the actual specimens. By most, indeed, examples will be remembered which conform almost perfectly to the descriptions. The question they suggest—and this is the deeper meaning to which we refer—is this: Is it not possible to do more to help the student who needs guidance? The need for discernment of personal character and for appropriate influence and direction are great in the case of many varieties of the type of "O. Goodman," and no less so in that of his brother, and of the very different "David." How many men there are who would do well and now do not if only they were observed, discerned, and watched and guided for a few months. The frequent examinations now adopted afford the means to a certain extent, but the work demands a special perseverance not always available. Yet such help should not be hopeless of attainment. With it much that is good would be made better, much that is failure would be changed into success, sometimes into signal excellence. No more forcible and no more eloquent indirect assertion of this need has, perhaps, ever been presented than the lecture we re-present to-day—to readers of wider knowledge and, let us hope, of greater wisdom, who can thereby but feel more keenly alike its force and power and beauty.

THE DUTY OF RAILWAY SURGEONS.

AN interesting paper was read by Mr. Clark Bell before the Section on Medico-Legal Surgery of the Medico-Legal Society of New York on Nov. 15th, 1894. The subject matter was the True Field of Duty of the Railway Surgeon. Mr. Bell incorporated with his propositions the written opinions of several leading American railway surgeons upon the line of action that a railway surgeon should take. In order that there may be no misunderstanding we may premise that Mr. Bell's paper seems chiefly to refer to cases in which the medical officer of the company is charged with the treatment of the injured person, who is in most instances an employé of the company. We entirely agree with Mr. Bell's contention that such officer should under no circumstances take part in the settlement of claims for compensation beyond drawing up an honest report of the condition of the person injured; and in common fairness a written copy of such report should be delivered to both parties. He ought on no account to advise as to the amount of compensation; for, however great his integrity and sense of justice might be, it would always be open to the construction that, to say the least, he was actuated by unconscious bias in favour of the company who employed him. The written report should be made soon after the alleged injury, and should anything further of importance transpire relative to the inquiry a supplementary report should be given. If this course were adopted either party, if dissatisfied, might call in an independent medical man. Moreover, such reports could be used as evidence at the trial of an action, and hence there would be the strongest motive for the railway surgeon not only to act fairly, but with due care. We repeat, that in cases like the above the surgeon should take no part in negotiations for a monetary settlement of a claim. With rare exceptions, railway companies in this country have permanent surgical officers of known repute and ripe experience, whose duty it is, not to attend employés, but to advise in cases of accident to passengers. Here his services are exclusively on behalf of the company. We have on a former occasion, referred to by Mr. Bell, asserted that a railway surgeon should not use his influence to induce a person to settle a claim, and, in fact, should never propose a settlement. We are still of opinion that it is perfectly equitable and consonant with the due discharge of his professional duty to adjudicate an award in conjunction

with the medical man on the other side, provided that both parties to the issue mutually agree upon such reference. If no settlement is arrived at it is understood that the negotiations were without prejudice. In such an event it is advisable that the particulars should not be divulged.

A STORY OF A HALFPENNY.

THE story in *Pickwick* of the boy who swallowed a bead necklace and rattled audibly, even when wrapped in a watchman's coat, is fairly equalled by an account that has just reached us of another boy who swallowed a halfpenny eighteen months ago. In spite of diligent search no trace of the coin could be found, and the boy himself gave no indication of having withdrawn a coin of the realm from circulation. He remained in good health, we are told, until a few days ago, when he had an attack of pneumonia, and during a fit of vomiting the coin reappeared. If the boy had not suffered in the interval the coin had; it was "very green," and the "engraving and date were very much worn." This is unfortunate, as it leaves an element of uncertainty in the case.

THE EVIDENCE OF THE SENSES.

MANY writers have at various times been attracted by the delightful absurdities which are often revealed by a calm and dispassionate investigation into the value of evidence in medical matters. There is a certain satisfaction in laying bare erroneous observations and in tracing the primary mistake which has led to the formation of false doctrines. There may even be pleasure in refusing to shout with the crowd, and in proving later that there was really no cause for excitement. But when there has really been a cause, and it has been misinterpreted by the multitude, how delightful to step in and set the world right, if only one can be sufficiently certain of one's own observations. It is of all things most difficult to distinguish between what we observe and what we think we observe, and this subject has seldom been developed with greater wealth of illustration than in the address by Mr. Bland Sutton, which will be found on another page (p. 12). His accounts of the acardiac fetus, of the button in the calculus, and of the marooned men are sufficiently grim and sufficiently neat to bear reproduction in many medical post-prandial discourses, even though they have a certain family likeness to the masterly deductions of the immortal Sherlock Holmes. To medical journalists it is a little depressing to find Mr. Bland Sutton considers that the "enormous number of incomplete records contained in periodical medical literature" is a source of much unsound knowledge; we venture to hope that in many cases the records are only "incomplete" because the patients recovered and the opportunity of confirming the diagnosis by post-mortem examination did not arise. Still, facts are facts, and even clinical observation, as the term implies, rests on the evidence of the senses.

TWO CASES OF ANEURYSM.

WE publish to-day two cases of aneurysm, each of which in its way is of special interest. Deputy Inspector-General Reid, whose name is associated with a particular method of treating external aneurysm, records a very successful case of popliteal aneurysm rapidly cured by the use of the elastic bandage. The special interest of this case lies in the fact that there was an aneurysm on each popliteal artery, and that they were successfully dealt with by different methods of compression—one by Carte's compressor, the other by Reid's method. He is of opinion that not only was his method more rapidly successful than the other, but that the cure

was obtained with permanent obliteration of a shorter length of the main artery. The fact is indisputable, but it is by no means clear that the responsibility for this rests with the treatment used. It is certainly quite unusual for the cure of a popliteal aneurysm, however brought about, to lead to obliteration of the whole of the superficial femoral artery, and it is to be borne in mind that the right aneurysm was distinctly smaller than the left; its cure would, therefore, take a shorter time to reach its final stage, and the consolidated sac would form a smaller mass than on the left side. Since the great improvement in the method and materials used for ligation of arteries, Reid's treatment and all other forms of compression have been much less employed. This case is an admirable example of the successful use of the elastic bandage, and its success was largely due to the care with which every detail of the treatment was carried out, particularly the protection of the clot. Brigade-Surgeon-Lieutenant-Colonel Stevenson's case was still more important. It was a case of a large aneurysm of the superior mesenteric artery, which was increasing rapidly, and in which surgical interference was thought to be necessary. Moore's method was employed, and about two yards of steel wire were passed into the sac. Unfortunately, considerable hæmorrhage subsequently occurred from the puncture in the sac, and the man died of syncope. This was in all probability a hopeless case. It would have been impossible to obtain cure of the aneurysm without obliteration of the superior mesenteric artery, and this would have caused gangrene of the small intestine. The introduction of steel wire into the sac of an aneurysm has not been a successful plan of treatment, and we think it will soon be abandoned altogether, for when cure is compatible with life, an aneurysm can generally be dealt with by other means.

'THE LANCET' RELIEF FUND.

THE sixth annual report of THE LANCET Relief Fund, together with the balance-sheet for the year 1894, will be found on p. 59. It will be seen that in the course of the year the sum of £344 has been granted in relief, by way of gift or loan (without interest), according to the exigencies of the several cases relieved, which numbered in all twenty-six instances. The Almoners have found it necessary again in their report to draw attention to the objects of the Fund; and the fact that as many as thirty applications proved upon investigation to be founded upon circumstances of a kind which do not fall within the defined objects of the Fund shows that no small degree of misapprehension still exists in reference to this matter. We make no apology, therefore, for referring in this place to the passage in which the Almoners request those readers of THE LANCET who may be asked to endorse applications before complying to peruse the application form and explain the precise object of the Fund to the applicants, especially to those whose cases do not come within the purpose for which the Fund has been established. In pressing this request upon our readers we are not actuated by any wish to avoid the labour and the pain of considering such applications and replying in the sense of refusal to the applicants, but our desire is, as far as possible, not to raise any unfounded hopes with their resulting disappointment. It is our pleasant duty in this connexion to express, in the name of the beneficiaries of the Fund, and in our own behalf, a warm appreciation of the services which have been rendered by the Presidents of the two Royal Colleges and of the General Medical Council in the capacity of Almoners of the Fund, and also to Sir Henry Pitman, who has again acted as its honorary auditor. It is not necessary to add that Sir J. Russell Reynolds, Mr. J. Whitaker Hulke, and Sir Richard Quain are men

upon whose time professional duties make a large demand, and that the performance of their voluntary task is not only valuable for the benefit which it confers upon some of the more unfortunate members of the professional brotherhood, and graceful for the evidence which it affords of a friendly feeling that raises the profession into a fraternity, but is costly to them for the personal sacrifice which it involves and therefore under every point of view worthy to be offered upon the altar of that "goodwill among men" which the season now so swiftly passing away has brought once more to mind.

DEGENERATIONS AFTER CEREBELLAR LESIONS.

A RECENTLY ISSUED volume of the Proceedings of the Royal Society contains an abstract of an important paper on this subject by Dr. Risien Russell. The object of the investigation was to determine which paths degenerate after ablation of one lateral lobe of the cerebellum and after extirpation of its middle lobe. After the former operation degeneration took place in all the peduncles on the side of the lesion and in the superior peduncle of the opposite side, but no degenerated fibres were found in the middle or inferior peduncles of the opposite side. As regards the degenerated fibres in the peduncles on the same side, those in the superior peduncle decussate in the posterior quadrigeminal region and pass to the opposite red nucleus and optic thalamus. None could be traced beyond this point. The degenerated fibres in the middle peduncle were found to pass chiefly to the grey matter on the opposite side of the pons. No support was found to Marchi's observation that degenerated fibres pass from this peduncle in the fillet and posterior longitudinal bundle to the corpora quadrigemina and periphery of the antero-lateral region of the spinal cord, and that some pass to the corpus striatum by the pyramidal tract. Some degenerated fibres, however, were found passing between the pyramidal bundles. Of the fibres which degenerate in the inferior peduncle, the majority occupy the lateral region of the medulla, becoming more and more scattered as they pass downwards. Below the superior pyramidal decussation the degeneration is represented by merely a few scattered fibres occupying the antero-lateral region of the cervical cord. Beyond this none can be traced. Degenerated fibres were found to pass from this peduncle to both inferior olivary bodies, although no well-marked tract to the opposite inferior olivary body, as described by Ferrier and Turner, was found. But Dr. Russell's results are in agreement with those of the above-named observers in affording no corroboration to Marchi's view that degenerated fibres pass from this peduncle to the ascending root of the fifth, the roots of the cranial nerves, and the spinal nerves. In regard to the degeneration in the opposite superior peduncle, the fibres affected represent fibres which degenerate in the cerebellum, passing from the seat of lesion across to the intact half of the organ and leaving it by this peduncle. These fibres occupy a special position in the peduncle, a part which is comparatively free from degenerated fibres on the side of the lesion and a part occupied by degenerated fibres on both sides when the cerebellum is divided into two by a mesial incision. These facts are regarded as a refutation of Marchi's statement that none of the peduncles contain commissural fibres. After extirpation of the middle lobe degenerated fibres were found in all the peduncles, a result which agreed with the observations of Marchi, but controverted those of Ferrier and Turner. Those in the superior peduncle occupied all parts of it, decussated in the region of the posterior corpora quadrigemina, and terminated in the opposite red nucleus. Those in the middle and inferior peduncles have a similar distribution and course to those resulting from ablation of one lateral lobe of the cerebellum. No evidence was found in support of Marchi's contention that degenerated fibres from this source pass to

the cranial nerve roots through the posterior longitudinal bundles and to the antero-lateral columns of the cord by way of the fillet. Dr. Risien Russell, agreeing with Ferrier and Turner, finds no evidence for the further statement made by Marchi that there is a distinct antero-lateral tract of degeneration throughout the spinal cord after lesions limited to the cerebellum.

OPEN SECTION FOR IRREDUCIBLE DISLOCATION AT THE SHOULDER-JOINT.

DR. W. N. KEENER, in a recent number of the *New York Medical Journal*, narrates the case of a man aged twenty-two years, very muscular, who, while attempting to mount an unruly horse, sustained a dislocation of the head of the humerus. Dr. Keener endeavoured to reduce it by manipulation, but failed, and tried all known methods of reduction without success. He decided that if reduction was impossible under an anæsthetic he would make an open section. The patient being anæsthetised another attempt at reduction was made, which proved unsuccessful; so an incision was made over the pectoralis major, which, being drawn downward, revealed the head of the bone deep between the pectoralis major and the pectoralis minor. It is stated that the capsule was not ruptured, but seemed to be pushed before the head of the bone; while closely hugging the anatomical neck, both anteriorly and posteriorly, were large, firm, cordlike bundles of fibres reinforcing the ligament proper. The anterior was the larger of the two. Both their humeral and scapular attachments were so close together that they were drawn very tense, and any attempt at reduction only seemed to draw them tighter. These were both divided with a scalpel and the bone went easily into position. The wound was closed and sealed with collodion, and healed by first intention. The joint appears to be as good as ever.

THE DIFFUSION OF SMALL-POX.

SMALL-POX has continued to be very quiet in London during the last fortnight of December, the fresh cases during that period amounting to only 5 and the fatal attacks to 2—one of a vaccinated and one of an unvaccinated adult—both belonging to the Marylebone sanitary area. Mr. Wynter Blyth, the medical officer of health for that parish, states that the disease still occurs in occasional single cases, but the epidemic prevalence has entirely gone. He has advocated very strongly the provision of such means of disinfection for the parish as will enable the officials to secure the proper treatment of clothing worn by all who have been exposed to infection and possessing only the clothes they stand in. The cases of small-pox remaining in the hospitals of the Metropolitan Asylums Board on Saturday last were 16 in number—a decline from 32 three weeks previously; and only 1 case was last week admitted, the admissions of the preceding week having been *nil*. In the Midlands matters are getting still brighter, the records for the latter half of December showing a falling-off in the number of attacks. Wolverhampton, West Bromwich, Walsall, and a few other towns have had experience of the disease, but only in a very slight degree. At Birmingham the cases in the two weeks were some 30, against 50 in the preceding fortnight, whilst the deaths were only 2, against 6. In Liverpool half a score of attacks and 2 deaths were registered. One death by small-pox was last week registered in Hull. In Edinburgh small-pox last month showed another decided increase, as many as 43 cases being notified in the first fortnight, new cases being also heard of in Leith and North Berwick. Within the space of a month 6000 vaccinations and revaccinations are estimated to have been performed in Edinburgh gratuitously. Similarly, in Dublin much vaccination and revaccination are being performed, the public being alarmed at the immense strides recently

made in the city by small-pox. On one day, Dec. 17th, no less than 40 cases of the disease were reported, bringing the total of a week to over 100 attacks heard of. In the week ended Dec. 15th the number of admissions to hospital was 88, a rise from 31 in the week immediately preceding, whilst in the following week there was a further increase to 116 admissions, with 12 deaths, in hospital in the fortnight, 4 of these deaths being of unvaccinated children and 1 of an unvaccinated adult. The deaths of vaccinated persons were all in adults. Despite the 91 discharges from hospital in the third week of December there yet remained under treatment 131 patients, exclusive of 126 convalescing patients in the South Dublin Union Small-pox Hospital at Kilmmainham. Up to that time the deaths in the city numbered 58 and the admissions to hospital just on 600.

THE CARTOGRAPHY OF MALARIA.

MALARIA in its distribution and intensity of incidence has of late years received much attention in Italy. Its haunts, indeed, constitute that real "Italia Irredenta" (unreclaimed Italy) which is far more deserving of the solicitude of her statesmen than that on which so much political agitation is expended. A glance at the latest accession to the solution of this great sanitary problem—the "Carta della Malaria," recently issued by the Direzione Generale della Statistica—will illustrate our meaning. This is a beautiful map of Italy (1:1,000,000), in which, by gradations of colours, we may realise the death-rate due to the "infezione malarica" and to the "palustral cachexia" throughout every commune in the kingdom in the three years beginning 1890 and ending 1892. In that period the mortality from malarial fever and the "cachexia palustralis" conjointly amounted to 49,407, corresponding on an average to fifty-four deaths yearly per 100,000 inhabitants. This proportion to population, however, varies within greatly extended limits. In the communes indicated on the map by a blue tint the annual mean of deaths from "infezione malarica" is 8 per 1000, such communes, moreover, being most numerous in the south-western tract of the island of Sardinia, in the south-east of Sicily, in the Basilicata (on the main land), and around the Pontine Marshes. As the map was constructed on the statistics of "deaths" from malarial fever, without regard to non-fatal cases from the same cause, we find that the provinces in which the fevers are certainly frequent, but rarely intense enough to cause death, are marked in light-coloured tints. The communes where this set of conditions prevails are considerable in number, and are situated mostly in the valleys watered by the lower reaches of the Po, exception being made, however, of the Veronese territory and of the Cremasco. Again, the Mediterranean littoral presents foci of malarial infection in varying degrees of intensity, the most severely visited being the territory around Grosseto, the Agro Pontino, and in the Salernitan region—the plain of Pæstum, so much frequented by tourists. A yet more interesting tract is that filled by the Eternal City. There we find that cases of death from malaria have, since 1880 to the present day, been rapidly diminishing in number. For instance, in 1881 there were in Rome 650 deaths due to malarial fever, in the following year 505, and in 1892 only 139. Passing from the city to the neighbouring Campagna, we find, of course, the intensity of the incidence of the malaria much higher. On the Adriatic slopes of the Apennines occurs again a severely visited zone, commencing above the promontory of Gargano and descending by Mollise, the Capitanata, and the Basilicata territories to the Ionian Sea, showing a mortality about as heavy as that of the Islands of Sicily and Sardinia. As affecting the general mortality of the Italian people, the figures from 1888 to 1893 maintain a pretty steady average—that is,

from fifteen to sixteen deaths a year. By those of our readers who are specially interested in the malarial problem, clinically as well as hygienically, this excellent map should be studied conjointly with the masterly treatise entitled "La Malaria in Italia, dei Dottori Sforza Claudio e Gigliarelli Raniero, Capitani Medici." These medical officers gained the Riberi prize ("primo premio") for this work, and in its published form have added to it seven large tables in chromo-lithography in illustration of the fully detailed exposition of the letterpress. The therapeutic value of remedies will be found to vary somewhat with the locality in which the fever is endemic—an induction not the least significant among the many in which Drs. Sforza and Gigliarelli's monograph abounds.

THE subject of the next triennial award of the Parkes Memorial Prize is "The Etiology, Prevalence and Prevention of Diphtheria." The prize consists of a bronze medal and a sum of seventy-five guineas. The competition is open to executive officers, on full pay, of the Navy, Army, and Indian Medical Services, except assistant professors at Netley, who are not eligible to compete during their period of office. Essays should reach the secretary, Parkes Memorial Committee, Royal Victoria Hospital, Netley, on or before Dec. 31st, 1897.

THE Secretary-General of the late International Medical Congress at Rome, Dr. Maragliano, informs us that the official proceedings of the Congress will be ready for publication in April next—that is to say, in one year from the termination of the Congress—an unprecedented piece of expedition.

THE Secretary of State for India has appointed Brigade-Surgeon-Lieutenant-Colonel William Roe Hooper, of the Indian Medical Department, to be President of the India Office Medical Board, on the retirement of Sir Joseph Fayrer, K.C.S.I.

WE learn that no fresh symptom of importance has occurred during the last few days in Lord Randolph Churchill's condition.

Pharmacology and Therapeutics.

SULPHANILIC ACID IN ACUTE CATARRH.

ACCORDING to Dr. Valentin,¹ sulphanilic, or paranalino-sulphonic, acid is an excellent remedy in acute catarrh. From thirty to sixty grains may be prescribed with a somewhat smaller quantity of bicarbonate of soda in ten times its weight of distilled water once or twice daily. The effect of a dose becomes apparent in about two hours, and the amelioration it produces may be expected to continue for a whole day or even more. When sulphanilic acid is taken for some weeks it does not appear to disorder the digestion or to produce any unpleasant effect, except, perhaps, slight diarrhoea.

TRIONAL IN SLEEPLESSNESS IN CHILDREN.

Trional, which is, chemically speaking, sulphonal with an additional ethyl group, has of late been used to a considerable extent by German practitioners in insomnia, especially that due to nervous and mental disease.² Its suitability for children has recently been pointed out by Dr. A. Claus of Ghent.³ He finds that it is especially valuable in the nightmares or "night terrors" to which nervous children are so subject, and also where the sleeplessness is associated with chorea or convulsions. It does not disturb the mental, respiratory, or circulatory functions, and acts rather beneficially than otherwise on the digestion. It does

¹ Pharm. Post, quoted in Nouveaux Remèdes, Nov. 24th, 1894.

² THE LANCET, July 28th, 1894.

³ Internationale Klinische Rundschau, No. 45, 1894.

not appear to be so suitable for alcoholic insomnia as chloral, and it has no analgesic action, so that it is of but little use to prescribe it when the sleeplessness results from pain. As to undesirable effects, in one case a child five years old, after a dose of 10 grains, was found the next day to walk unsteadily, the power of coördination being interfered with. The dose was diminished to 7½ grains, and no further trouble was experienced. These smaller doses were continued for a week, when the child was able to sleep in its usual manner. This was the only instance in which any unpleasant action was caused. The doses recommended by Dr. Claus are as follows: For children of less than twelve months of age, 3 to 6 grains; for those between one and two years, 6 to 12 grains; for those between two and six years, 12 to 18 grains; and for older children up to ten years, 18 to 23 grains. The powder can be given in warm milk, or, better still, in jam or honey, half an hour after supper, or at latest a quarter of an hour before bedtime. It may be prescribed nightly for some considerable time if necessary, as it does not appear to lose its effect when given continuously.

URICEDIN IN URIC ACID DIATHESIS.

Dr. Hugo Langstein of Teplitz-Schonau strongly recommends a preparation named "uricedin" in uric acid diathesis. This substance consists of citrate of potash and sulphate of soda, together with chloride of sodium and citrate of lithium. It is white and granular, and it dissolves in water. It was brought under the notice of the Twelfth International Medical Congress by Dr. Mendelsohn of Berlin, who stated that 300 grains might be taken daily without any ill effects and with very marked benefit to patients with uric acid diathesis. Dr. Langstein now writes¹ that he has employed it in fifty cases of gout during the last bath season, with excellent results. He considers that it is much more certain in its effects than the alkaline mixtures that are commonly prescribed or than mineral waters. It may be used in conjunction with the ordinary régime of baths and water-drinking at a German *Bad* such as Teplitz, and it is very useful as an after-treatment for the patient who has been to the baths in the summer to take during the succeeding winter. He was first led to employ this preparation in the treatment of his patients on account of the excellent results he had obtained with it in his own case. He had been suffering from increased uric acid in the urine associated with very severe smarting urethral pain for a long time, and had only been able to obtain temporary improvement from ordinary alkaline treatment and from a variety of mineral waters, and at last decided, with considerable misgiving, to make a trial of uricedin. At first he took 38 gr. per diem. The day after commencing this treatment he excreted more uric acid than usual, but on the third day the reaction was neutral, and no more uric acid was found for another week, after which a glass of beer brought it on. All this time the smarting pain in the urethra had continued, and then, as no calculus could be found to account for it, the daily dose was gradually increased until 150 gr. were taken. The pain then diminished in a very marked degree, and the uric acid secretion was only observed at times when the uricedin was discontinued.

DIPHTHERIA AND SERUM THERAPEUTICS.

EXPERIENCES OF THE TREATMENT.

DR. BAGINSKY, who, we believe, was one of the first to advocate the bacteriological diagnosis of diphtheria, contributes a paper¹ in amplification of his remarks in the recent debate at the Berlin Medical Society. He insists upon the careful study of each individual case subjected to serum treatment as of more value than statistics, which at present can only be based on small numbers. On the diagnostic value of the bacteriological test of the presence of the Löffler bacillus he has no doubt, and confirms the statement of the presence of the organism in cases not showing the symptoms of diphtheria, but none the less liable to transmit infection. He urges that if care be taken in the preparation of portions of membrane for cultivation the bacillus may

be found in a larger proportion of apparently diphtheritic affections than has been averred. As regards the treatment, he says that he did not abandon his previous local and general measures when adopting it, but combined the old and new methods. The amount injected depended on the age of the subject and the duration of the disease prior to commencing the treatment, a larger dose being given to the cases coming later under treatment. He found, however, that no effect was produced in some cases, nor could it be expected; for these were cases in which the intensity of poisoning was so great as to irreparably affect the organs of the body before any antitoxin could operate, however early it was given. They are truly malignant cases, such as most infective diseases present—e.g., scarlet fever. Although he had given doses above the average he had seen no ill-effects produced, with one exception. Many patients had a trivial rash, some had also symptoms of joint inflammation. One of the cases which presented a rash died suddenly fourteen days after discharge from hospital with symptoms suggestive of cerebral embolism—an event which he had known to occur after diphtheria prior to the introduction of the serum treatment. As to nephritis, it was not more marked in these cases than in diphtheria as he had known it before; indeed, there was mostly less albuminuria and fewer casts in the serum-treated cases than he was wont to see. One patient, with cardiac complications, to whom the serum had not been given, had hæmaturia, possibly due to renal embolism, and in the case of another in whom diphtheria supervened in the fourth week of scarlet fever the nephritis abated after injection of serum. At the same time he thought attention should be paid to symptoms of cardiac failure, which seemed to be disproportionately frequent in the recent epidemic, for most of those dying under the treatment died from cardiac asthenia. He concludes by saying that it is too early yet to pronounce definitely upon the value of the treatment.

Dr. Mya (Florence) has treated eighteen cases² with Behring's serum, with an average of two injections each. Of these, two were "pure anginal diphtheria" and recovered; five were "diphtheria with incipient croup," recovered; ten were "diphtheria with developed croup," in all tracheotomy was performed—two died; one of "croup, associated with staphylococci and streptococci," fatal. He admits that the number is too few for statistical inference, but says the treatment is scientific and harmless, that it is antidotal, and not to be expected to remedy the changes already produced in the organs by the toxins.

NEPHRITIS IN DIPHTHERIA.

In the *Deutsche Medicinische Wochenschrift* (1894, No. 51) there are two papers on this subject. The first is by Dr. Troymann of Frankfort-am-Oder, who relates an instance of acute hæmorrhagic nephritis in a subject treated by the serum. This was one of twenty cases so treated in the Frankfort town hospital under Dr. Gläser, and among them albuminuria was frequent. The child was eight years of age. Treatment commenced on the third day of illness, injections being repeated on the two following days. Two days later the membrane had disappeared, but within a week it reappeared and another injection was given. This was followed by a rash and albumen in the urine, which contained blood and casts. But four days later the urine was free from albumen. It is pointed out that the time at which the nephritis appeared seemed to throw doubt on its being due to the diphtherial virus. But it is noteworthy that a fortnight after his discharge from hospital the child came back with well-marked palatal and limb paralysis.

The other paper is by Dr. Schwalbe, one of the editors of the journal, who gives a parallel case in a child, occurring in 1890, at Friedrichshain Hospital, and therefore before the serum treatment was in vogue. He points out the great frequency of albuminuria in diphtheria, the rarer but not unknown occurrence of acute nephritis, and deprecates the tendency to attribute to remedies on their trial the supervention of complications which, though rare, are known occasionally to arise under any treatment.

MEDICAL MAGISTRATE.—Mr. William Bridgett Pritchard, L.R.C.P. Lond., M.R.C.S., has been placed on the Commission of the Peace for the city of Manchester.

THE LANCET

SPECIAL ANALYTICAL AND SANITARY COMMISSION

ON THE

INCANDESCENT SYSTEM OF GAS LIGHTING.

THE idea of utilising coal gas for illuminating purposes was first carried into effect by Murdoch in 1792, but he could not have entertained the slightest conception of the enormous industry which this system of lighting, which was also demonstrated in London at the close of the last century, was destined to become long before the end of the succeeding century. So crude, however, was the gas first employed for this purpose that the evolution of injurious products of combustion from it, due chiefly to foul sulphur compounds, threatened to extinguish the system at its very inception. But the introduction of improved methods of purification and production saved it from so untimely an end, and spared the life of an industry which is now well-nigh indispensable to the existence of the civilised world. It is interesting to reflect how even medicine, if coal-gas lighting had not been established, would have been bereft, possibly to the present day, of many of its valuable agents. What antiseptics, for example, are more largely employed or more highly valued in the treatment of disease than the series of phenols obtained exclusively from coal tar? or what more valuable antipyretics, &c., are at the physician's disposal than those which coal-tar products have furnished? And what study, again, more than that of these interesting derivatives has given greater impetus to pharmacology in adding to our knowledge of the constitution and structure of bodies and so enabling us to make remedial measures more scientific and exact? Again, our eyes would never have beheld the endless series of beautiful colours made from coal-tar products; and how different would have been the complexion of everything connected with fabric had not coal tar provided us with a starting point from which these things have been obtained? To the idea of utilising coal gas as an illuminant, therefore, we owe all these benefits; and just as at one time coal gas was the only product of the destructive distillation of coal upon which any value was set—whereby, in consequence, so many valuable by-products were lost—so now investigators have been led to inquire as to whether, by existing methods of lighting, we realise the full value of coal gas as an illuminating agent, or, in other words, whether we extract by present methods all the radiant energy or light which it is capable of giving.

It is well known that coal gas is luminous when it burns because it contains certain hydrocarbons, but that, in order to get the maximum illuminating power from it, burners of special construction must be employed. It is only, however, within quite recent years that any really serious attention has been devoted to the improved structure of gas burners with the object of utilising to the fullest extent the luminosity which the mere burning of coal gas by itself affords. Types of these are illustrated in the steatite bathing or fishtail burner, the Argand, and regenerative burners, all of which yield a more or less brilliant light, rich in red and yellow rays, which, as is characteristic of coal gas flames, possess a strong diffusive power. These all require, however, a gas of definite illuminating value, which may be referred to the presence of hydrocarbons, chiefly of the paraffin and olefine series. The illuminating value of coal gas varies with a number of conditions, as, for example, the kind of coal employed, the temperature used in distilling it, and so on; but the coal yielding the highest illuminating value is Newcastle Cannel (so called because it gives a gas up to the candle power prescribed by Parliament). Now that the supply of this variety of coal is sensibly diminishing, and

the demand for coal gas steadily increasing, other coals are used, and the purified gas obtained from them is subsequently enriched with water gas, impregnated with highly luminous "oil" gas. This, as we shall presently see, is an important point when we come to consider the principles underlying the working of the incandescent burner, which has recently undergone considerable alteration and improvement. Indeed, so rapidly is the incandescent system of gas lighting being introduced amongst us, so popular is it becoming on the score of its economy and better illuminating power, that the importance of an investigation into its merits from the health point of view cannot be questioned. We propose, therefore, in the present article to deal chiefly with this aspect of the new system, but we may add a concise account of its history, and more especially of the way in which its essential parts are constructed, since there are involved in the various stages of its structural progress several highly scientific processes of a pretty as well as interesting kind.

Curiously enough, the incandescent gas-burner had its origin in the attempts of Auer von Welsbach to discover a substitute for the carbon filament of the incandescent electric lamp, which would incandesce in air without being destroyed or burnt, and thus to obviate the necessity of enclosing the filament in a globe exhausted of air. How far these attempts were successful we do not know, but the "mantle" composed of rare earths, which is the essential feature of the present burner and which incandesces so brightly in the atmospheric gas flame (Bunsen's burner), was, we imagine, not the least fruitful result of the investigation, judging from the satisfactory progress which has lately been made with it. The incandescent gas-burner, when complete, may be said to consist simply of two essential parts (Figs. 1 and 2); the first an ordinary but carefully adjusted burner of

FIG. 1.

FIG. 2.

the Bunsen type, in which air is mixed with the gas before it burns—generally in the proportion of 30 of gas to 70 of air—producing a substantially colourless or slightly blue flame; the second a mantle (Fig. 2), composed of certain rare earths prepared with the utmost care and skill, which is suspended in the flame to the best advantage (Fig. 3) by means of a forked support of magnesian silicate, itself luminous when hot. The flame and mantle are enclosed in a chimney of glass or other transparent vehicle, as seen in Fig. 4, which, though not absolutely essential for the production of light,

effectually serves to protect the fragile mantle from accident, while at the same time it keeps the flame perfectly steady. The mantle is prepared by the following very interesting process. A cotton thread is first woven into a tubular shape in network form, washed previously in diluted ammonia, to remove grease, and then in water containing a little hydrochloric acid, and finally in distilled water, and dried. The knitting is next cut up into suitable lengths, a piece of net sewn round one end of it to form the top, and then saturated with a solution containing the nitrates of the rare earths, zirconium, lanthanum, thorium, and cerium, and dried on glass rods. An asbestos thread is then passed through the top of the mantle, forming a loop to attach the mantle to the support. The lanthanum and zirconium contribute whiteness to the light, and the thorium a bluish-white light, and the cerium a red, which adds to the diffusive power of the light. One of the sources from which the oxides employed are obtained is *monazite*, which yields thorium, lanthanum, cerium, and didymium. *Orthite* is another source from which cerium and didymium are obtained. Most of these minerals are said to come from Norway; but they are now found, with the exception of *thorite*,

FIG. 4.

FIG. 3.

in large quantities in America. The mantle is drawn into shape by being pulled over a model of the desired form, and the flame of a Bunsen burner is afterwards applied to the upper portion of the mantle, which, catching fire, burns slowly downwards, shrinking considerably in length as the cotton burns away, leaving a thin network skeleton of the oxides of the metals, which, on being placed in the flame of a Bunsen burner, becomes at once incandescent, emitting a bright steady light. After holding the mantle over the Bunsen flame for a few minutes to get it into shape, it is "seasoned" by burning it over a high-pressure burner, and finally dipped in a solution of collodion, dried, and placed in boxes, when it is ready to be sent out. The film of collodion serves to strengthen the mantle for transit purposes. It is readily burnt off by placing it upon the support on the burner, and lighting it with a somewhat reduced flame before the chimney is put in position. In a few minutes it is completely burnt off, and the chimney may be placed over it.

"Incandescence" is the brilliant glow given out by certain refractory bodies when they are heated up to a definite point. It is the partial conversion of heat into light rays.¹ A platinum wire held in the Bunsen flame becomes first

invisibly hot, then partly visibly hot or red hot, and finally white hot, when it incandesces, or emits powerful white light rays. The luminosity of the coal-gas flame, it may be remarked, is really due to the incandescing particles of carbon which are set free from the acetylene derived from the decomposition of the hydrocarbons of the gas during the stages of combustion. Thus the series of changes taking place in luminous flames are explained by Professor Vivian Lewes in the following interesting, and probably correct, way. In the inner zone of the flame the constituents of the gas undergo various decompositions and interactions, which culminate in the conversion of the heavier hydrocarbons into acetylene, carbon monoxide being also produced; and these, with the products of combustion and residual hydrogen, pass into the next phase of action. Here the acetylene formed in the inner zone becomes decomposed by heat with liberation of carbon, which at the moment of production is heated to incandescence by the combustion of the carbon monoxide and hydrogen and gives luminosity to the flame. Since, then, the luminosity of the coal-gas flame is due to incandescing particles of carbon set free in the flame, and which are subsequently burnt up, and the light of the electric incandescent lamp consists of incandescent rays emitted by the carbon filament which is heated by the electric current, it follows that the nature and character of the light from both are the same. Thus, compared with the electric arc-light both exhibit a reddish-yellow tinge, and both possess a higher degree of diffusive power than the pure white light itself.

In the Welsbach burner, on the other hand, the incandescence is due to the heating of a network of oxides of certain rare earths, which emit at the temperature of the Bunsen flame a bright, steady, and powerful white light. It affords, in fact, an admirable illustration, and is probably the best result ever obtained, of the conversion of heat into light rays. Thus, the Bunsen flame is very hot, possessing no luminous value, but by allowing it to play upon certain refractory and resisting bodies the heat undergoes a metamorphosis into the closely allied phenomenon of light. It is the production of radiant energy at the expense of calorific energy. In considering the Welsbach burner from the health standpoint, and bearing in mind the principles just laid down, we may regard it as consisting simply of an ordinary Bunsen burner over the flame of which is suspended a network of incombustible material that is intensely light-giving when raised to the temperature of the Bunsen flame.

First, then, let us consider the Bunsen burner, or, what is the same thing, the Welsbach burner without its mantle. It is well known that the conditions of combustion in the Bunsen or atmospheric burner are more favourable, and the formation of complete products more certain, than in the luminous flame. The Bunsen flame, for example, is without luminosity because "experiments show that the nitrogen acts in the normal flame by so diluting and protecting the hydrocarbons that a far higher temperature is needed for their decomposition; and this action gives time for the oxygen of the air to consume them, without liberation of carbon, and hence without luminosity" (Lewes). In the luminous gas flame, however, as already explained, the decomposition of acetylene occurs in the outer zone, giving rise to heated and therefore luminous particles of carbon, so that it is extremely probable that traces of this gas, as well as carbon monoxide, are given off from this flame—an anticipation which delicate analyses confirm. The changes in the atmospheric burner are not only more complete by the introduction of air, but they occur at an earlier stage. In Table IV. will be found the results of certain experiments in which various burners, including the luminous and non-luminous, were tested side by side with the view at the outset of deciding this important point. Subsequently we shall deal with this at greater length; suffice it to mention here that the results were decidedly in favour of the atmospheric or Bunsen burner.

The complete combustion of a definite volume of coal gas

descends by an atmospheric burner of peculiar construction, whereby the gas and air are heated before combustion takes place. In the Lewis system, again, a small hood of platinum, or alloy of platinum and iridium, is used, which is brought to incandescence by the Bunsen burner, in which the air is admitted under pressure. In the Sellen system a cone of metal gauze is used, and heated with a Bunsen burner of similar construction to the last. Lastly, there is the system of Fahnehjelm, a Swedish chemist, which is in extensive use, and in which small pencils of magnesia, or a mixture of magnesia and zirconia, are attached to a small frame in the form of a comb, which is suspended over the flame of a water-gas-burner, and is immediately brought to a high state of incandescence.

¹ It should be mentioned that there are other systems in use which depend upon the light emitted by an incandescing body. In the Clamond system of incandescent gas lighting, for example, a basket or hood of magnesia and zirconia is employed, which is heated to incan-

must, of course, on theoretical grounds, give rise to the production of exactly the same amount of burnt gases in whatever burner the gas is burned. Obviously a cubic foot of gas burned completely in a batsawing, Argand, or atmospheric burner would give, as end products, the same amounts of carbonic acid and water. It follows, therefore, that if the consumption of gas be low the evolution of products will be proportionally reduced, so that, apart from the economical point of view, a burner that consumes a relatively small amount of gas, to say nothing of the superior light it may yield, must be preferable on that account from the hygienic point of view. This, therefore, is exactly what is secured in the Welsbach burner by reason of the employment in it of an atmospheric burner which consumes at the most, but generally less than, four cubic feet of gas per hour. The indisputable hygienic advantages thus gained are strikingly illustrated in Table I., the results of which are based upon the varying rates of consumption of different burners. The amount of combustion products yielded by oil lamps in the same time makes an interesting and instructive comparison.

TABLE I.—*Calculated Relative Quantities of Carbonic Acid Gas (CO₂) produced by different Burners, based on 1 cubic ft. of Coal Gas giving 0.52 cubic ft. CO₂.*

Burner.	Consumption in cubic feet.	Cubic ft. of CO ₂ evolved per hour.	Number of human adults producing same amount of CO ₂ per hour.*
Welsbach (atmospheric burner) ...	3.5	1.82	3.03
Argand	6.0	3.12	5.20
Bray, No. 5 batsawing... ..	6.0	3.12	5.20
Belge oil lamp (16 candle power) }	2.08 oz. oil per hr.	2.91	4.85
Hinks' duplex (candle power undetermined) }	2.90 oz. oil per hr.	4.00	6.66

* Based on one human adult exhaling 0.60 cubic foot CO₂ per hour.

Thus, calculating on the quantity of carbonic acid gas expired hourly by the human adult and on the quantity produced on burning a known quantity of coal gas or of oil, we find that while the Welsbach burner, consuming 3½ cubic

feet per hour, would be equal to the exhalation of at least three persons, other forms of burners are equal to over five persons, while an oil lamp of 16 candle power would also be nearly equal to five individuals, and another oil lamp of increased candle power, which is very generally in use, to a number of individuals approaching seven—that is to say, more than double the equivalent given by the Welsbach light. These results are not entirely speculative, and we may proceed to describe some experiments we made with the view of putting them to practical test. The results are contained in Table II., which hardly needs explaining. The experiments were made in a very small room, 10 ft. long, 10 ft. high, and 6 ft. wide only, the usual crevices having first been closed. The amount of carbonic acid and the temperatures at two points—one just beneath the ceiling and the other at breathing level—were ascertained before the experiment, and repeated at intervals of an hour each after the burners had been lighted, the experiment being stopped after three hours. Two burners were fixed on the walls at a height of 6 ft., and were 9 ft. apart in opposite corners—that is, at each end of the diagonal. These conditions represent, of course, a very extreme and exaggerated case, owing to the size of the room and the use of two burners in it, but the trials were strictly comparative, and the errors introduced in the analyses and observations were reduced in proportion as the products were greater and the rise of temperature higher. In the last experiment an oil lamp was placed upon a table 3 ft. high, as this was considered to represent the actual conditions of practice. The lamp was carefully weighed before and after the experiment, the difference in weight giving, of course, the amount of oil (kerosene) consumed.

The results are of extreme interest and importance in regard to the health aspect of the case. The relative vitiating and heating effects of several types of burners are best seen, however, in Table III., which we shall deal with presently. To return to Table II., the chief points calling for notice are as follows: the relative effects of a Welsbach burner with and without a mantle are especially instructive, as affording some information of distinct value as to the chief differences caused by the introduction of a mantle into the flame. The sum total products should of course be the same, since the amount of gas consumed was the same. The mean amount of CO₂, as a matter of fact, was, as the table shows, as nearly as possible identical. But by the introduction of the mantle into the flame it is evident that there occurs a concentration of the CO₂ close to the ceiling, while there is, as we should expect, a corresponding and very decided diminution at the breathing level. We conclude, therefore, that the plain Bunsen flame (enclosed in a chimney) produces a quicker and more decided distribution of the burnt

gases or products in the room, owing, no doubt, to the greater freedom of space around the flame and the consequently increased draught up the glass chimney. On this explanation the introduction of the mantle into the flame would naturally reduce the rate of draught through the chimney. The same is true of the temperature, which after the first hour was raised by the Welsbach burner with its mantle only 6° at breathing level, but in the case of the burner without the mantle it was raised 10°. Indeed, the increase of temperature, as might be expected, appears *pari passu* with the carbonic acid. So far, then, the Welsbach burner is distinctly more satisfactory in its effects upon the air of a room at breathing level than even the plain atmospheric burner. When we look at the effects of the Argand and batswing burners, of course the carbonic acid and temperature increase enormously in accordance with the greater consumption of gas. The Argand vitiates the breathing level somewhat sooner than the batswing, in consequence, no doubt, of the impetus given to circulation by the use of a chimney. This is true also of the increase in temperature. Finally, the oil lamp effects a gradual and general distribution of both the heat and carbonic acid produced, the amount of these being the same both at the ceiling and breathing level. It should be observed in addition, however, that though with the oil lamp, as might be anticipated, the rise of temperature is not so great as two Welsbach lamps (the proportion of hydrogen in oil, the chief heat-producing constituent of coal gas, being relatively small), yet the mean amount of carbonic acid produced was almost exactly the same after three hours; so that the vitiation of air with carbonic acid gas by one Welsbach burner giving over 50 candle power light and consuming 3½ cubic feet of gas is less than one-half that produced by an oil lamp of 16 candle power, and consuming a little over 2 ounces of oil. We have here a striking fulfilment of the requirements of theory in Table I., and therefore some distinct evidence of the accuracy of the experiments.

Looking now at Table III., we see at a glance the merits of

omitted searching for unburnt gases, such as carbon monoxide or acetylene, which, if found, howbeit in small traces, would afford emphatic ground for objection to the general adoption of a burner from which these poisonous products are shown to escape. We preferred to exaggerate the ordinary conditions under which a burner is used still more than before, so as to focus any possible impurities of this sort, and in order to be quite sure that even the smallest traces would not escape our tests. The experimental procedure of this section of the inquiry was as follows. The burners (in the case of the Welsbach two in number, but of the rest only one) were lighted and placed in a small chamber 3 ft. 1 in. x 3 ft. 1 in. x 2 ft. 4 in. (with no provision for any appreciable ventilation or outlet for the gases) for eight hours, during the whole of which time the air taken from above the burners was aspirated first over potash and soda lime to remove carbonic acid and sulphur compounds, then through sulphuric acid to remove ammonia, and, finally, through a dilute solution of blood. At the end of eight hours the experiment was stopped, and the blood examined with a delicate spectroscope. To preclude any doubt whatever as to the presence of carbon monoxide the blood was further treated in the following manner. Fresh air was caused first to pass through a solution of palladium chloride to remove organic or other chance impurities, then through the blood, the temperature of which was gradually raised by means of a water bath, and, finally, through a third tube containing chloride of palladium. Any carbon monoxide absorbed by the blood during the aspiration of the combustion gases would thus be displaced and would cause a darkening in the palladium solution due to separation of the metal. Acetylene was also searched for, the solution of ammoniated silver nitrate being employed for the purpose. The results obtained are given in the following table (IV.), in which two Welsbach burners (total consumption 7 ft.) were compared with one each (consumption 6 ft.) of the other types.

TABLE III.—Increase of Carbonic Acid and of Temperature per Candle Power.

Burner.	Con- sumption.	Candle power.	Mean increase of temperature in one hour.	Increase of tem- perature per candle power.	Mean increase of CO ₂ in one hour, parts per 10,000.	Increase of CO ₂ per candle power.	Increase of CO ₂ per cubic ft. of gas consumed.	Increase of tem- perature per cubic ft. of gas consumed.
Two Welsbach	7	50+40	63·5–53=10·5°	$\frac{10·5}{90·0}=0·116°$	32·8	$\frac{32·8}{93}=0·365$	4·8	1·6°
Two Argand	12	16+16	72–53=19°	$\frac{19}{32}=0·590°$	60·0	$\frac{60·0}{32}=1·900$	5·0	1·5°
Two Batswing, Bray, No. 5.	12	9·6+9·6	68·5–53·0=15·5°	$\frac{15·5}{19·2}=0·807°$	55·0	$\frac{55·0}{19·2}=2·86$	4·6	1·3
One Belge Oil Lamp	2·08 oz. oil per hour	16	60·5–53·0=7·5°	$\frac{7·5}{16}=0·468°$	25·2	$\frac{25·2}{16}=1·56$	—	—

the Welsbach burner contrasted with various other burners from the point of view—i.e., the hygienic—which prompted the present inquiry. We cannot ignore the fact, in the light of the results contained in this table, that, quite apart from economy of gas and the increased light value secured, the Welsbach burner affects the atmosphere far less for evil, judging from the carbonic acid and heat, than any other existing type of burner. Thus, while the increase of carbonic acid per candle power is only 0·365 in the case of the Welsbach light, it is 1·9 in the case of the Argand, 2·86 in the batswing, and 1·56 in the oil lamp; and the increase of temperature with a Welsbach burner per candle power is only 0·116°, compared with the Argand, 0·59°, the batswing, 0·807°, and the oil lamp, 0·468°. (In this estimate the candle power of the Welsbach is taken as low as 45 candles, whereas it reaches frequently as high, as will be seen later, as 60 candles). The figures in the two columns at the right of the table should obviously accord with each other, since the increase of carbonic acid and of temperature should be the same for the same quantity of gas consumed. As a matter of fact, the figures coincide fairly well; at least, they are as close as can be expected, the experiments may be expected to allow.

TABLE IV.—The Results of Tests with various Burners for Carbon Monoxide (CO) and Acetylene (C₂H₂) in the Products of Combustion.

Burner.	Blood test (carbon monoxide).	Palladium chloride for carbon mon- oxide in pro- vious blood.	Ammonia silver nitrate test for acetylene.
Two Welsbach burners without mantles = atmospheric burner, consumption 7 cubic feet per hour	Negative.	Negative.	Negative.
Two Welsbach burners (complete), consumption 7 cubic feet per hour	Negative.	Negative.	Negative.
One Argand burner, consumption 6 cubic feet	Negative.	Negative.	Negative.
One Bray batswing, consumption 6 cubic feet	Slight indica- tion.	Slight indica- tion.	Doubtful.

It will be seen that, except in the case of the batswing, no distinct evidence of undesirable products in the burnt gases

was found. Even when the gases were aspirated for hours straight from the chimney of the Welsbach burners, neither of the poisonous gases carbon monoxide or acetylene could be detected. The Argand burner gave the same satisfactory results.

Finally, Table V. deals with the relative illuminating power of various burners and the loss of light sustained by the use of tinted and other chimneys with the Welsbach burner. The light of the Welsbach burner is intensely white and brilliant, being equal, for only $3\frac{1}{2}$ cubic feet of gas consumed, to a maximum of 60 candles and a certain average of 45 candles. (It should be observed, as is shown in some instances in Table V., that no advantage in light is gained by running the gas at a higher speed; on the contrary, by frequently reducing the gas an increase of luminosity is obtained.) For some purposes it is desirable to reduce this intensity so as to make it less affecting to the muscles of accommodation of the eye. A diminution of light may be produced, and also an alteration in its tone, according, of course, to the kind of chimney used. This loss is given in Table V., and, although it amounts to some considerable extent, yet it still gives a greater luminosity than other burners, and for a much smaller consumption of gas. The ruby chimney gives a light of twenty-seven candles,

* This burner was used in the remaining experiments.

which in appearance approaches the Argand gas flame very closely, while the mica chimney, though absorbing a small amount of light, is unbreakable. It may be freely recommended for general adoption, therefore, as likely to prolong the life of the mantle and to dispense with the really serious inconvenience of the breaking of the glass chimney. The glass rod chimney is an excellent device for producing a good dispersive effect. Like the electric arc light, the Welsbach incandescent light is very rich in the violet or active chemical rays of the spectrum, and it has consequently a low diffusive power; but, on the other hand, it serves very effectually as a source of artificial light for photographic purposes. It is also excellently well adapted for the illumination of objects on the microscopic slide and for certain operations in analytical chemistry in which change of colour is taken to indicate chemical change. Owing, again, to its extreme brilliancy it

proves an excellent search-light for the exploration of the larynx, fauces, or nasal cavities. Lastly, the photometric measurement of a mantle that had been three months in constant use is interesting as showing how satisfactorily the illuminating power is maintained.

In considering, in conclusion, the systems of artificial lighting that are in vogue at the present time, the incandescent system of electric lighting must, of course, rank first from the point of view of health, since it affords a soft, agreeable light, without giving rise to any vitiation of the air; there is no combustion, and consequently there are no products of combustion, complete or incomplete. From the same point of view we are bound to place next, in the face of the result of our present inquiry, the incandescent gas light in its improved form. It is even less productive of carbonic acid gas than the average oil lamp, and consumes not quite one half less gas than the existing type of burners, giving rise, therefore, to the evolution of half the heat and half the amount of carbonic acid gas, while its illuminating power expressed in candles is more than three times as great as the best ordinary gas-burners or the incandescent electric lamp, each of which does not generally exceed 16 candle-power, unless a very great expense is no object to the consumer. We are far from saying that the incandescent system of gas-lighting has attained to the highest pitch of perfection; still we are well within bounds when we regard it as the system of gas lighting which utilises most efficiently and most economically the full powers or duty of coal gas as an illuminating agent. Some have expressed fears that the burner is a delicate instrument—much too delicate—for the part it is destined to fulfil; but we have found with ordinary care—and care is well worth a little exercise in view of the enormous advantages the system affords—that these fears need not exist. We understand that in practice the average life of a mantle, taking risk of breakage into consideration, is between three and six months, but the mantles have been frequently known to last over a year, at the end of which time their lighting efficiency was still good. One more important point, already slightly touched upon, is that, in spite of its high illuminating powers, this burner does not require a gas possessing any special illuminating value itself; and as it is the maintenance of a high illuminating value which contributes in a large measure to the cost of coal gas, the general adoption of the incandescent system of gas lighting would probably lead to the production of a cheaper gas—possessing little illuminating power, but adapted equally well for the incandescent gas-burner—which would then contrast more favourably with coal as regards cost for heating purposes. The production of a cheaper gas since the introduction of the incandescent system of lighting has, we believe, engaged the serious attention of engineers, chemists, and others, and we may expect to hear more on this important question before very long. To hygienists this is an extremely important aspect of the incandescent gas system, inasmuch as it is obvious that the introduction of cheaper gas, by its more extensive employment for fuel, would tend to free London from the reproach of being a city which, during the greater part of the winter, is enveloped in vilely suffocating fogs. There is therefore, we think, a future for the new system of far-reaching importance to the community.

THE LANCET LABORATORY.

THE HOUSING OF THE POOR AT BUDAPEST.

WHAT THE INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY DID NOT SEE.

(FROM OUR SPECIAL CORRESPONDENT.)

AT Budapest, or rather at Pest, there are some magnificent buildings in broad and lengthy streets. In the neighbourhood of the Hungarian capital there are men of great wealth, who possess splendid estates. The members of the International Congress of Hygiene and Demography, who recently met in that town, were shown all the beautiful public monuments, the various institutions, colleges, theatres, &c., and were entertained with princely hospitality at the seats of the nobility living near the capital. This was all very well in its way and very pleasant, but the Congress was supposed to gather together men earnest in the cause of sanitary reform.

The Hungarians are an intensely patriotic people; but unfortunately their patriotism is so exaggerated that it degenerates into Chauvinism. Thus everything that could, even by a stretch of imagination, be construed as creditable to the Hungarian nation was proudly shown to the members of the Congress. This gratifying task was so well accomplished that not a few, even among the most prominent of the foreign delegates, actually went away with the impression that Budapest was a well-administered and healthy town! Certainly statistics were given that prove a very different state of things, but these were lost in the crowd of communications, and nothing was done to bring them home to the delegates. If, however, such congresses meet, not in the most convenient town, but in various towns and countries, it is for the purpose of strengthening the cause of sanitary reform in these different and distant centres. On such occasions the local sanitary reformers have a splendid opportunity of laying bare the sanitary defects which they are seeking to remedy and adding to the force of their own reclamations the opinion of eminent hygienists from all parts of the world. Now Budapest stands out among the capitals of Europe as one of the very worst towns that exist in respect to the housing of the working classes and of the poor. This grievance prevails in all great centres of population, but is especially acute at Budapest; consequently it was natural to imagine that one of the first objects of the organisers of the Congress would be to conduct the members into the cellar dwellings, the overcrowded tenements, and the slum property of Budapest. These visits could have been followed by such a debate and by the adoption of resolutions of so conclusive a character as to thoroughly awaken the conscience of the country and compel the Government and municipality to take action. Thus the holding of the Congress at Budapest might have helped to improve the condition of the homes of the poor, and such a result would have rewarded the effort of travelling so long a distance. Nothing of the sort, however, was done; and though, in one of the numerous Sections, Dr. Josef Schwartz of Budapest formulated a most substantial and conclusive impeachment of the town of Budapest, the Sections for the most part were so poorly attended that many communications read to them found no echo. Even the voice of Dr. Jacques Bertillon was lost in the wilderness of innumerable papers, speeches, and Sections; yet what this most eminent demographer stated was startling enough, and had the facts been generally known to the Congress many members would have suggested the advisability of making investigations while on the spot. Dr. Bertillon stated that in 1891 the population of Paris amounted to 2,424,705 persons, and out of these people 331,976, or 14 per cent., were living in overcrowded houses or lodgings. In 1885 there were 1,315,387 people in Berlin, of whom 363,960, or 28 per cent., were in overcrowded tenements, &c. For Vienna in 1891 the figures of the population were 1,364,548, of whom 387,000, or 28 per cent., were in overcrowded dwellings. At Moscow in 1882 there was a population of 750,867, of whom 236,649, or 31 per cent., were in overcrowded dwellings. At St. Petersburg in 1890 there were 956,226 inhabitants, of whom 442,508, or 46 per cent., were suffering from overcrowding. But what shall we say of Budapest? Will it be believed that this beautiful town, about which such praise was sung at the Congress, is not only more, but much more, overcrowded than the worst of the towns just mentioned? Yet Dr. Bertillon submitted to the Congress figures showing that in 1881 Budapest had 360,551 inhabitants, of whom 250,601 were living in overcrowded houses. This gives the enormous proportion of 71 per cent. of the inhabitants of Budapest as suffering from the effects of overcrowding, and makes out that the capital of Hungary is in a much worse condition than even the two capitals of Russia. Of course there are exceptional circumstances that account for the exceptionally unfavourable position of the inhabitants of Budapest. The town has developed and the population increased so rapidly of late that it has been aptly described as the Chicago of Central Europe. (Fig. 1.) Due to growth by this growing prosperity, vast multitudes of workmen and labourers have thronged to the capital, thus crowding all available dwellings. Not only are the dwellings in a deplorable condition, but the streets are filthy and the air is impure. The average rent of dwellings at Vienna, consisting of one single room, is 50.99 fl. per annum. This is equal to an annual rent of 5.40 fl. per square metre of floor surface, or 1.73 fl. per cubic metre of space. For two-roomed tenements the rent is proportionately cheaper—namely, 97.80 fl., or 4.08 fl. per square metre and 1.47 fl. per cubic metre. For three rooms the rent was still cheaper—namely, 145.75 fl. or 3.71 fl. per square metre and 1.31 fl. per cubic metre. Dr. Schwartz calculates that at Budapest the average rent for one room is 122 fl., or 3.40 fl. per square metre and 3.07 fl. per cubic metre. The two-roomed tenement is set down at 144 fl., or 6.37 fl. per square and 2.35 fl. per cubic metre. Thus it will be seen that the rents charged at Budapest are very much higher than the already extravagant rents of Vienna. The above figures submitted to the Congress, but scarcely noticed by its members, led me to make a personal investigation. I appealed to Dr. Josef Schwartz, as the author of the most remarkable paper on the subject, and he very obligingly devoted two or three days to taking me round some of the worst districts of Budapest. First we went to a place called the New Watch House, on the outskirts of the town, where there need not have been any overcrowding as there was much waste space around and a considerable amount of land was not yet built upon. Here were a series of houses divided into tenements, forming large inner courts and various kinds of buildings, including even an artist's studio. Under the main entrance there was a horrible stench coming up between loose planks that were placed over an open drain. This entrance formed a long archway, and into this passage, right over the foul drain, was the only window of the first lodging we entered. It was a single large room; the rent was 90 fl. per annum. A woman and four children lived here. From this room, with the aid of matches, we found our way along an absolutely dark corridor. There were no windows whatsoever to light this passage, and a cavernous, damp odour prevailed. At the end we penetrated a tenement consisting of two rooms, one of the rooms being nearly filled with a grand piano. Seven persons lived here, most of them musicians, and the rent was 150 fl. per annum. Outside there were stables, a large number of goats and poultry were wandering about, and under a distant archway there were four closets, which were frequented by the inhabitants of three courts. These closets were filthy in the extreme, and being under an archway were dark and had no direct ventilation. Near to these closets we came upon five adult persons sleeping together in a very small room; and in a room upstairs I counted six beds. This latter tenement consisted of two rooms—the larger room with the six beds and a smaller room where an old woman was at work making sacks. By this occupation she said she could earn from 2 fl. to 3 fl. per week. The rent for these two rooms was 150 fl. per annum. Close by a very small private chapel had been divided in two horizontally by building a floor across the middle, thus converting it into two tenements. The upper portion, consisting of one long narrow room under the roof, was occupied by five persons. The atmosphere within was absolutely stifling. Close to this chapel tenement I found a mangle in a dark sort of lumber space at the end of a passage in which there were three closets, so that the foul emanations from the badly constructed drains could be readily absorbed by the damp linen about to be mangled; indeed, there were a great many laundresses in this unwholesome quarter. Another room I found to be below the level of the court; it was damp and had an earthy smell. There was but one very small window, and this was not opened "because the baby was ill."

In the same part of the town and not far from the New Houses of Parliament, now in course of construction, I visited a court inhabited exclusively by Slavs. The Slavs have come in droves to Budapest. They are very cheap, generally live together, and do labourer's or navy's work. On two sides of the court there were small, low houses of the cottage type, and in one of these cottages there were six people inhabiting one small room, for which they paid 180 fl. rent per annum. The third side of the court, or little square, was walled off from the street by a wooden boarding, while on the fourth side there was one of the most remarkable structures it has ever been my fate to see in a large town. (Fig. 1.) It was a wooden hut constructed apparently by amateur builders who had utilised any odd planks and bits of wood that could be picked up. In photographing this shanty

dwelling at Vienna, consisting of one single room, is 50.99 fl. per annum. This is equal to an annual rent of 5.40 fl. per square metre of floor surface, or 1.73 fl. per cubic metre of space. For two-roomed tenements the rent is proportionately cheaper—namely, 97.80 fl., or 4.08 fl. per square metre and 1.47 fl. per cubic metre. For three rooms the rent was still cheaper—namely, 145.75 fl. or 3.71 fl. per square metre and 1.31 fl. per cubic metre. Dr. Schwartz calculates that at Budapest the average rent for one room is 122 fl., or 3.40 fl. per square metre and 3.07 fl. per cubic metre. The two-roomed tenement is set down at 144 fl., or 6.37 fl. per square and 2.35 fl. per cubic metre. Thus it will be seen that the rents charged at Budapest are very much higher than the already extravagant rents of Vienna. The above figures submitted to the Congress, but scarcely noticed by its members, led me to make a personal investigation. I appealed to Dr. Josef Schwartz, as the author of the most remarkable paper on the subject, and he very obligingly devoted two or three days to taking me round some of the worst districts of Budapest. Close to this chapel tenement I found a mangle in a dark sort of lumber space at the end of a passage in which there were three closets, so that the foul emanations from the badly constructed drains could be readily absorbed by the damp linen about to be mangled; indeed, there were a great many laundresses in this unwholesome quarter. Another room I found to be below the level of the court; it was damp and had an earthy smell. There was but one very small window, and this was not opened "because the baby was ill."

I persuaded one of the Slavs inhabiting the court to stand close against the hut so as to show how low it was. It will be noted that the door is wider at the bottom than at the top and consequently cannot be properly closed. But the thin planks which constitute the walls do not fit better than the door. In many places the hand can pass between them. In spite of the encumbering lumber and the darkness I managed

FIG. 1.

Wooden Hut at Budapest in the Court tenanted by Slavs.

to photograph the interior. In the small bed there depicted sleep a man and a woman. (Fig. 2.) On the bed is the man's stock-in-trade, a basket loaded with crockery. It will be noticed that the bed stands on the bare earth. There is no flooring whatsoever, and when it rains the earth becomes quite wet with its soakage from the surrounding land. But

FIG. 2.

Interior of the same Hut.

a good deal of the rain also enters this habitation through the numerous holes in the roof and walls. The light shining through these holes and the open spaces between the badly fitting planks forms white spots and white lines in the photograph. Some straw for packing the crockery, broken wooden cases, old rags, and tattered clothing filled up much of the

space within the hut, though apart from the bed there was no other article of furniture. The day of my visit was grey and grisly, and everything about was damp, cheerless, and devoid of any trace of comfort. The hut suggested a temporary structure reared by a shipwrecked mariner on the shores of a desert island. That it should be the home of a man and a woman in the great and prosperous commercial and political capital of a civilised European country seemed almost incredible. To sleep in such a place is to risk being frozen to death, for, as is the case with all Central European towns, Budapest suffers from the extremes of heat and cold. This is not, of course, shown by the average temperature. From 1871 to 1890 the annual average temperature was 9.9°C., the warmest month (July) was 21.4°C., and the coldest (January) 1.9°C. below zero; but this is the average for many years. The average temperature for July, 1865, was 24.8°C., and for December, 1879, the cold was equal to 10.5°C. below freezing point. The greatest extremes known were of heat 35°C. in July, 1870, and of cold - 26.6° in December, 1879. Let us imagine what must be the condition of people who are only protected from such extremes of temperature by a few thin planks of wood loosely nailed together. The cutting draughts passing through this hut from all sides certainly provide

FIG. 3.

Entrance to Mansion in the best quarter of Budapest, showing Grated Window of Cellar Tenement below.

plenty of air, but they destroy all sense of comfort, at possibility of warmth or efficient shelter.

It may be argued that this hut was but a temporary makeshift, though it has been in existence a good long time, that it was meant only for cattle or for lumber; but this is no reason for allowing human beings to dwell in it. In any case, there are close at hand large blocks of dwellings recently constructed, and for them there is no excuse for insanitary conditions. There must have been some municipal control over the plans and designs of these vast workmen's dwellings. One of these block buildings which I visited contained sixty-three children belonging to forty different families, each family being located in a separate tenement. The square block has in its centre a square yard, after the fashion of a Spanish *patio*, with balconies all round at each floor. The first of these galleries or balconies is on a level with the pavement of the street, and the court a storey below. Thus the house is built down as well as up, and there is a whole floor divided into numerous tenements below

the level of the street. The only light and air are from the *patis* or inner well-like court, or else from very small skylights on a level with the street causeway. No special provision is made for the ventilation of these underground dwellings; they were dark and damp, and at this low level, where there is little or no circulation of air, there were a number of closets, which, though trapped, were so rarely flushed that the traps were full of solid soil and the pans filthy. Thus, in the most recently constructed artisans' dwellings, tenements are deliberately built that can never receive a direct ray of sunlight, that must ever remain in a state of semi-darkness, that cannot be free from damp, because the outer walls rest against the earth below the street pavement, that cannot be efficiently ventilated, and must evidently and for all these reasons be absolutely unwholesome. According to the official report of the Director of the Statistical Office of Budapest, the well-known demographer, Professor Körösi, the living in underground dwellings shortens human life by from two to three years, and he further declared that at Budapest the prevalence of infectious epidemics in underground dwellings is 60 per cent. more frequent than in other dwellings. Yet in spite of this authoritative statement there were in 1890 in Budapest 104,047 dwellings or tenements of which 5.09 per cent. were underground.

Nor is it only in poor quarters and in artisans' dwellings that cellar tenements will be found. These also exist in the wealthiest parts of the town. Within a stone's throw of the best club of Budapest, in a magnificent street proudly called Magyar-street, there are several cellar dwellings. The accompanying photograph shows the only light and air inlet given from the street to one of these cellar tenements. (Fig. 3.) The handsome window of the ground floor, and the stately entrance door indicate that this is a luxurious and high-class dwelling-house. But there is a small aperture protected by iron bars and on a level with the causeway. This is the only window of a tenement below. This cellar dwelling consists of one room lighted by the little aperture in question. The room measures 4.20 by 4 metres and is 2.20 metres high. At the end furthest from the street there is a kitchen measuring 3 by 3 metres and 2 metres high. This kitchen is absolutely dark. Dr. Schwartz calculated that the rent paid for this cellar dwelling amounted to the fabulous sum of 5.66 fl. per square and 2.66 fl. per cubic metre of space, or in round figures £12 a year. In the same building there were several other equally dark and dear underground tenements. Such places, though only suited to serve as cellars for storing wine, are thronged by poor people who live there and overcrowd even these wretched abodes. Under such circumstances it is not surprising that the death-rate at Budapest is high; the cause is self-evident. Of course overcrowding in a city that is rapidly developing cannot be easily checked, but surely as new houses are being built on all sides the authorities can prevent the construction in them of dwelling rooms that cannot by any possibility become wholesome habitations. If the authorities—in view of the indifference and ignorance of the population on such subjects, or of the interested opposition of building speculators—had not the courage to deal with this question they could have profited by the presence of the International Congress of Hygiene and Demography at Budapest to gain the moral strength of which they seem to be deficient. They might have invited the whole Congress to express its opinion on the necessity of abolishing cellar dwellings. This discussion might have been preceded by a visit to some of the cellar dwellings of Budapest. Such an excursion would not have redounded to the honour of the Hungarian people, but it would have done credit to the sincerity and humanity of all concerned. It would not have supplied the material for flattering comments on the progress accomplished at Budapest, but it would have provided sharp and incisive arguments to force forwards the cause of sanitary reform, which, in respect to the housing of the poor, has been scandalously neglected.

(To be continued.)

Egyptian sanitation are, as in two former reports, very plainly pointed out in trenchant language which admits of no possibility of doubt. While urging the necessity of an increase in the inspectors, and pleading for the appointment of an additional European, which has since been granted to him, Surgeon-Lieutenant-Colonel Rogers writes: "In time of epidemic disease such as cholera the present organisation can only lead to a breakdown, and this I wish to be clearly realised. In dealing with the ordinary epidemics of the country, especially typhus fever, cases are constantly occurring where no inspectors are available, and the inadequate measures taken by incompetent medical officers lead to a loss of life which an inspecting staff would largely diminish." Now that typhus fever has become so rare in England it is interesting to note that in Egypt there were forty-three outbreaks as compared with twenty-two reported in 1892. This increase in the reported numbers may be partly due to greater activity on the part of the native officials. Altogether 1407 cases were notified, including 243 deaths. They were spread all over the various provinces, from the Soudanese frontier to Alexandria, but many of the epidemics were caused by relapsing fever, which the native medical men can hardly yet diagnose from typhus fever. Moreover, at least 108 cases and twenty-six deaths must be deducted from the figures above because they were due to enteric fever among the British troops. Measles was present during the year, chiefly from February to July, and caused 473 deaths out of 1215 cases reported. Small-pox accounted for 191 deaths, out of 746 patients, rather more than half of whom were inhabitants of Lower Egypt. The disease, when it appears, plays great havoc among the blacks, who are never vaccinated in the Soudan. It is very satisfactory to find that in Cairo itself, where civilisation ought to be further advanced, there were only eight cases during the year. To those who are interested in the medical welfare of the Egyptians it is satisfactory that not only do the hospitals to which English medical men are attached grow in popularity, but that also some of the provincial hospitals are now sufficiently filled, though the staff consists entirely of native medical men, most of whom have been recently educated at Tantah, where there is the greatest improvement of this kind: the in-patients for 1892 numbered only 979, while in 1893 there were 1196. At the Kasr-el-Aini Hospital, where the annual overturn is nearly 5000, there were 976 surgical operations, besides 1037 ophthalmic operations. The sum of £22,000 is now being spent upon repairing and partially rebuilding this old hospital, and Surgeon-Lieutenant-Colonel Rogers is more than ever convinced that it would have been true economy to have entirely condemned the old building and built a new hospital on modern plans. A small infectious hospital, consisting of two pavilions for twenty-two beds, has been built in the desert near Cairo, and to this is attached a public disinfecting station. At Alexandria also a new pavilion for twelve beds for infectious diseases has been erected. The lunatic asylum has been provided with new kitchens, baths, and laundry, and it is hoped that permission will now be given for an English psychologist to be appointed in order to study lunacy as seen in Egypt, and also to introduce some form of necessary employment and exercise for the patients. The drainage schemes for Cairo and Alexandria are still being studied without any immediate hope of fulfilment. It is estimated that for Cairo alone the cost will be over a million pounds, and Surgeon-Lieutenant-Colonel Rogers meets the financial difficulty by strongly advising the Egyptian Government to spend half that sum upon the partial drainage of certain quarters of the city. In commenting upon some of the faults of native medical men in the Sanitary Department, the Director-General reminds the Government that no lasting improvement in the officials can take place so long as instruction at the medical school is given only in Arabic. "After leaving the school," as Professor Virchow has put it, "the entire literature of civilised nations is a closed book to the students." The only criticism which we feel tempted to make upon Surgeon-Lieutenant-Colonel Rogers' able report is where he is inclined to recommend that the course of medical education be reduced from six years to five years, on the grounds that students in law and engineering have a course of only four years. The whole tendency of medical studies is to become more expansive every year, and we believe we are right in saying that one year of the enforced term is devoted to those scientific subjects which should properly be studied before the professional course begins.

appears that the only towns in which any attempt is made to distribute filtered water are Cairo, Alexandria, Port Said, Suez, and Assiout. In Cairo the filtration by bacteriological tests is satisfactory, but unfortunately only a small minority of the inhabitants have filtered water laid on to their houses. In Alexandria the absence of proper filtration by the water company has been exposed by the reports of Dr. Bittar, the German sanitary inspector attached to the municipality, and in consequence some new filters are now being constructed there. In the chemical laboratory it is curious to note that rather more than one-fourth of the year's analyses for the various Government departments had reference to the discovery of *cannabis indica* (hasheesh). Attention is called to the existence of nineteen cases of poisoning, mostly by arsenic, which came before the Medico-Legal Commission. It is difficult to say how many other cases there may be which defy detection. The Egyptian, like the native of India, sometimes becomes a professional poisoner and is fond of using datura for his victims, but fortunately not in lethal doses. We are told that there are 3000 villages in Egypt provided with barbers and midwives, but 1000 others have no similar provision. It would be interesting to know how the practice of the medicine men and old women of these thousand villages is carried on, and also who is responsible for the certificates of death. Surgeon-Lieutenant-Colonel Rogers concludes by pressing upon his chiefs the importance of creating a bacteriological laboratory and of providing some day a necessary refuge for the lepers and the incurables of Egypt. There are several appendices to the report, including an interesting one by Mr. Littlewood, the chief veterinary inspector. From it we learn that there were during 1893 six cases of human rabies reported and only one

case in a dog. Two Englishmen and a native underwent treatment in Paris, and so far are quite well. Rabies seems to have been introduced during the last few years into Lower Egypt from Europe; it would seem to be quite time to establish a dog tax, and more stringent control over the ownerless dogs. Eighteen cases of glanders and farcy were reported in Cairo and Alexandria, and an extensive trial of mallein was carried out in doubtful cases. Influenza has been very rife among horses, mules, and donkeys, though in previous epidemics among human beings in Egypt the stables escaped free. At the Cairo slaughter-house 113 cases of tuberculosis were detected, and the camels furnished the very large proportion of 4 per cent. of this number. The slaughter-houses and the animals of Egypt are now better cared for than the incurable paupers who by reason of blindness, lameness, or other infirmity are unable to earn their livelihood. These unfortunates are at the mercy of the Wakfs, or Ecclesiastical Commissioners, and though their condition was fully exposed to the Council of Ministers ten years ago, and again a year ago by Surgeon-Lieutenant-Colonel Rogers, nothing has been done in the way of reform. "The building is in a wretched state of repair and in a most filthy condition, swarming with vermin." Four male and two female attendants are supposed to look after 224 inmates, including 107 lunatics, who are visited by a native medical man twice a week. The condition of this "Te Kia," which is at Tourah, only eight miles from Cairo, is enough to show us what care the Egyptians take of their co-religionists, and we tremble to think what would be the condition of the hospitals of the country if it were not for the handful of English medical men attached to the sanitary service of Egypt.

THE LANCET RELIEF FUND.

SIXTH ANNUAL REPORT OF THE ALMONERS.

THE LANCET Relief Fund, which has for its Almoners the President of the Royal College of Physicians of London (Sir J. RUSSELL REYNOLDS, Bart., M.D., F.R.S.), the President of the Royal College of Surgeons of England (Mr. JOHN WHITAKER HULKE, F.R.S.), the President of the General Medical Council (Sir RICHARD QUAIN, Bart., M.D., F.R.S.), Mr. THOMAS WAKLEY, F.R.C.S., and Mr. THOMAS WAKLEY, jun., L.R.C.P. Lond., with Sir HENRY PITMAN, M.D., F.R.C.P., as Honorary Auditor, came into operation on the 1st of February, 1889.

In presenting the sixth annual report, the Almoners think it well again to direct attention to the objects for which the Fund was established.

The Fund is sustained solely by the Proprietors of THE LANCET, who provide every January the sum of at least £300, and is administered free of cost, with the object of affording immediate pecuniary assistance to registered medical practitioners, or to the widows or orphans of members of the profession in cases of distress and emergency, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require.

When the Fund was inaugurated considerable misapprehension existed as to the precise objects for which it had been established; and, as a result, the majority of the earlier applications, being cases of *chronic* distress, and not coming, therefore, under the designation of *emergency*, could not be entertained. Attention was called to this fact in THE LANCET of Feb. 16th, 1889, in the following words:—

"We are requested by the Almoners to state that, from the character of a number of the applications received, both personally and by letter, for relief, it is evident that in many cases the object for which this Fund has been established is not quite clearly understood; and, if relief had been afforded in the cases of those who suffer from chronic distress, the Fund would have been completely exhausted within the first few days of its existence. They would therefore be greatly obliged if those readers of THE LANCET who may be asked to endorse applications would carefully peruse the Application Form and explain the precise object of the Fund to those applicants whose cases do not seem to come within the scope of the purpose for which the Fund has been established; which is, to afford prompt aid to registered medical practitioners, or to the

widows or orphans of members of the profession, who, in consequence of the supervention of some unexpected exigency, which is not likely to recur, have pressing need of immediate and temporary pecuniary relief," and who, it may once more be pointed out, are likely to be permanently benefited thereby.

The balance in hand at the end of 1893 amounted to the sum of £133 4s. On Jan. 1st, 1894, the Proprietors of THE LANCET placed to the credit of the Fund the sum of £300. During the course of the year repayments of loans to the amount of £21 have been made. The sum of £344 has been granted in relief either by way of loan or of gift, leaving a balance of £110 4s., as per bank pass-book.

There have been considered altogether during the twelve months ending Dec. 31st, 1894, 56 applications for relief (the number the previous year having been 48). In 26 cases assistance was afforded, either as a loan or as a gift, according to the request of the applicant, the amounts of the grants ranging this year from £5 to £30.

The following are extracts from a few letters received from some of the recipients of the Fund:—

186.—"I wish to thank the Almoners for the help their loan has been to me, as it was one of the means which has helped me to resume my work."

217.—"I beg to return you my very best thanks for the generous gift of £— from the above Fund; and I can assure you, gentlemen, that the grant will prove of much service to me in overcoming my difficulties. I enclose a letter of thanks to the Almoners; but, if in order, I would feel it a favour if you could specially convey to the Messrs. Wakley my deep gratitude for the kind gift which emanates from them. I trust in time to be able to report to them a successful issue out of my difficulties."

221.—"The Almoners of THE LANCET Relief Fund.—I beg to offer you my very sincere thanks for the loan granted to me, which will entirely relieve my pressing necessities, and without which I am utterly at a loss to know to what source I could have turned for help."

223.—"I am unable to sufficiently thank you for £— so kindly sent from THE LANCET Relief Fund. You cannot imagine of what use it will be. I enclose receipt with very many thanks."

232.—"I return you my grateful thanks for the donation of £— received last evening. Indeed, it came in an acceptable

moment. Another week's rent due to-day, with old arrears at a standstill—this gift has prevented landlord taking extreme measures; and, secondly, I have a little boy very ill; so, indeed, it seemed a godsend, with but one sixpence in the house. Again thanking you —."

237.—"Be good enough to transmit to the Almoners of THE LANCET Fund the expression of my sincere gratitude, not only for the generous aid granted me, but for the promptitude of their truly kind assistance. It will be a satisfaction to them to know that their benevolent act has materially helped to calm the breakers which threaten to engulf a struggling professional brother."

238.—"I have received your kind note with enclosed cheque for £— from the Almoners of THE LANCET Relief Fund. I feel very grateful for the kindness so promptly attended to in sending me the required relief, and also for the liberality of time given for the repayment of loan; but, should I be fortunate enough in securing a permanent situation, it will be my wish and pleasure to repay the debt long before the time stated. I enclose the agreement signed, also

the receipt for cheque for £—. And again sincerely thanking you for my wife and myself," &c.

246.—"Allow me to thank you very much for your great kindness to me and my little ones. I am truly thankful; I cannot say more. My case is a very hard one, my husband being ill so long that we are sadly reduced, so much so that not one of us had a second change of clothes, so that you may know how truly thankful we all are for your kindness."

248.—"I beg to offer you my most grateful thanks for your generous gift received this morning, as I am absolutely penniless, and only for your goodness in thus so promptly responding to my application should have been in great distress. Again thanking you very much, pray accept my warmest thanks for so promptly submitting my request to the Almoners of THE LANCET Relief Fund, who have so generously responded to the same. I was quite penniless, so you can well imagine my thankfulness."

J. RUSSELL REYNOLDS.

I find by the Bankers' Book that the actual balance on Jan. 1st, 1894, to the credit of the Fund was £133 4s., to which the sum of £300 was added by the Proprietors of THE LANCET on the same day. The balance at the Bankers' at the present date is the sum of £110 4s. I have also checked the receipts for disbursements and find the above account strictly accurate. December 28th, 1894.

HENRY A. PITMAN, Hon. Auditor.

CHRISTMAS AT THE HOSPITALS.

As far as circumstances permitted high festival has been held in the wards of many of our London hospitals during the Christmas season, and praise is due both to the medical staff and to the institutions concerned for their efforts to lighten the burden of the sufferers, whom

On the locker to each bed... for

plum pudding, &c., with wine, was served in all the wards at 12.30, and from 2 till 4 o'clock in the afternoon the hospital was open to visitors so that the patients could have their friends with them. The Christmas tea was served soon after 4 o'clock, the wards being illuminated. After tea the resident medical officers and the nursing staff, assisted by some friends, gave short concerts in the wards, excepting those wards where any of the patients were thought to be too ill to bear the music. These entertainments were most enthusiastically joined in by the patients, and were very successful. The whole day passed delightfully, resident medical officers, students, sisters, and nurses all successfully endeavouring to make others happy and themselves thoroughly happy in the process.

On Christmas Day the patients of the hospital were all dressed in their best, and the day was spent in the most cheerful manner. The patients were all very happy, and the day was a most successful one.

room, from which all patients who were well enough to come down received a gift, while for those confined to the wards a bran-pie was taken round, and every patient, nurse, and servant of the institution received a present. It has been decided to defer for a few weeks the concert given by the Middlesex Hospital Musical Society, under the leadership of Dr. J. J. Pringle, who is organising a brilliant entertainment of song, recitation, and instrumental music for the amusement of the unfortunate sufferers in the hospital.

St. George's Hospital.—The usual Christmas festivities were indulged in, and those who were well enough to eat them were supplied with roast beef and plum pudding on Christmas Day. On the evening of the 27th an entertainment for the patients was given, and a liberal tea presided over and served to the patients by the lady visitors and their friends provided. A musical entertainment was also held in all the wards where the patients were not too ill to suffer in consequence. Christmas trees were provided for the amusement of the children, and the beautiful presents of toys received from *Truth* were distributed. Everything was done as far as possible to give the patients a happy Christmas season.

St. Thomas's Hospital.—The only festivities which took place this year were carol singing on Boxing evening and the pleasures associated with a Christmas tree, which was decorated in the Victoria Ward on the following day.

London Hospital.—The annual Christmas tree and entertainment were held on New Year's Eve.

Royal Free Hospital.—A very enjoyable day was spent at this hospital on Dec. 25th. The seven wards were decorated by the nurses. As a third of the beds were closed in consequence of alterations there were only 120 patients in the hospital. A dinner consisting of the usual Christmas dishes was served at 12.30, after which a briar pipe and an ounce of tobacco, the gift of Mr. J. M. Grant, a member of the board, were given to each of the men, and fruit was provided for the women and children. A special invitation was sent by the matron to each child who had been an inmate of the hospital during the year and to the friends of the patients, and a large number put in an appearance between two and three o'clock, when as guests they received every consideration. After tea, at which all the visitors were present, several entertainments were given by the nurses in the different wards. Each patient and each of the young guests received a suitable present, those for the children being hung on the Christmas tree.

Great Northern Central Hospital.—Christmas Day and Boxing Day at this hospital were celebrated in the customary manner by the decoration of each ward by the nurses and convalescing patients with holly, ivy, and mistletoe, supplied in abundance by numerous friends of the hospital living in the neighbourhood. The patients, with few exceptions, thoroughly enjoyed a Christmas dinner of turkey and plum pudding, and an extensive distribution of toys made all the children happy. On Boxing Day an impromptu concert was organised in the Henry Quin Ward by the staff, and was much enjoyed by the patients. The annual entertainment for the patients will not, however, take place until Jan. 15th, when a series of *tableaux vivants* and a concert will be given under the direction of Mrs. Herbert Allingham.

The German Hospital.—The wards of this hospital were tastefully decorated, and on Christmas Eve the trees were illuminated, presenting a very pretty spectacle. Carols were sung, and a distribution of suitable presents was made to the patients, nursing staff, and attendants.

Hospital for Consumption, Brompton.—At this institution Christmas was, as usual, kept in exceedingly pleasant fashion. The galleries and wards were beautifully decorated with evergreens by the willing hands of sisters and nurses. The dinner consisted of turkeys and plum puddings and wine. Early on Christmas morning the nurses sang carols on the galleries, and later there were services in the chapel. On Friday evening the usual Christmas tree distribution took place in the entertainment room, every inmate receiving a handsome gift, through the kindness of the Misses Haddy and many other friends of the institution.

National Hospital for the Paralyzed and Epileptic.—At this hospital every effort was made to make Christmastide bright and cheerful. Books and cards were distributed at breakfast time, and after dinner and dessert a round of festivities was begun in the wards, including the performances of a negro troupe organised by the house physicians. Friends were admitted on Boxing Day, and on the Thursday there was a grand entertainment in the large hall, with a distribution of useful gifts arranged by the Lady Superintendent, in which

every patient shared. A Christmas tree will be provided and ward teas and ward concerts take place during the succeeding fortnight, and the festivities will conclude with a display of magic and ventriloquism on Jan. 15th.

Samaritan Free Hospital for Women and Children.—The Christmas festivities at this institution were held on Dec. 27th, and began with a musical and dramatic entertainment provided by the following *artistes*: Mr. John Thomas (the Queen's harper), Mrs. John Thomas, Miss Orgill, Miss Napier, Miss and Master Pelle, Mr. and Mrs. Hugh Bulkeley, Madame L'Estrange, Miss Elsie Macmillan, Mr. W. H. Probert, Dr. Walter Tate, and Mr. Hutchons. They gave a very successful and highly artistic performance, and their efforts were much appreciated by the patients and nurses who were fortunate enough to be able to attend. A carol was sung by the nurses. After the entertainment the annual distribution of Christmas gifts took place, and, thanks to the liberality of a number of kind-hearted friends, a goodly stock of useful and ornamental articles were obtained for the occasion and distributed amongst the patients, nurses, and servants of the hospital.

City of London Hospital for Diseases of the Chest.—On Christmas Day a dinner, consisting of the usual Christmas fare, was provided for the patients at this hospital, at which some of the committee of management and governors were present. Christmas cards, books, periodicals, &c., were distributed, dolls, toys, &c., provided by *Truth* and other friends, being given to the juvenile patients. In the evening a musical entertainment took place which was much appreciated.

East London Hospital for Children.—The Christmas entertainment for the patients of this hospital was held on Dec. 29th.

Victoria Hospital for Children.—Her Royal Highness Princess Louise has signified her intention to be present to-day (Friday) at the Christmas treat to be given at this institution.

Dreadnought Seamen's Hospital.—On Christmas Day service was held in the hospital chapel at 10.30 A.M., and the Christmas dinner, consisting of turkey and plum pudding, was served to the patients at 12.30 P.M. On Dec. 28th there was a concert and dance for the nurses, commencing at 7.30, on which occasion Mr. P. A. Nairne, the deputy chairman, brought his private band. On Jan. 3rd there was a Christmas tree for the children who had been patients during the year or were present in the wards, and on a date early in January Mrs. Freck. Smith of Lewisham Hill will give an entertainment to the patients in the recreation room.

The Cancer Hospital, Brompton.—On Christmas Day the whole of the patients who were well enough to partake of Christmas fare were regaled with turkey, plum pudding, and other such luxuries. On Jan. 2nd high tea was held with the usual Christmas tree amusements. This hospital provides regular entertainments (either dramatic or musical) throughout the winter season about once a fortnight.

Among the provincial institutions the staffs of which ministered to the happiness of the sick inmates were the Bristol Royal Infirmary, the Children's Hospital and the Eye Hospital in the same town, the Nottingham General Hospital and the Children's Hospital, the Fleming Memorial Hospital, Newcastle, and the York County Hospital. Christmas Day at the Royal Berks Hospital was spent in a very happy manner, game, turkeys, and other Christmas fare being supplied in abundance.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Staffordshire County Sanitary District.—Dr. George Reid, in his annual report for 1893, follows his usual practice of dealing with the district reports under subject-headings, instead of, as is done by some county medical officers, giving a synopsis of each report separately. Dr. Reid, however, supplies at the end of his report excellent tables which practically summarise the work done in each sanitary district in the county, and it is easy to obtain at a glance any information that may be required as to any given place. A special

report upon the isolation provision of the county is embodied in the report before us, and Dr. Reid observes, that in any scheme for providing hospital accommodation for the county, it must be laid down as a principle that small-pox cases may not be isolated in the same hospital as other infectious diseases. Dr. Reid also refers to the necessity for making proper provision for trained nurses, and he rightly states that it is not surprising that the public hesitate to submit to isolation under the circumstances existing in many districts. A very full and interesting account is given by Dr. Reid in his report of some experiments which he undertook for the county council with a view to determine the possibility or otherwise of effectually treating the sewage of slop-closets when the rain water is carried off by a separate system. Experiments were made both with polarite and magnetone as a filtration medium, and with ferrioum and superphosphate of lime as a precipitant. Without discussing in detail the experiments, it may be said that Dr. Reid arrived at the conclusion that for undiluted slop-closet sewage precipitation by either of the precipitants referred to, and filtration through either magnetone or polarite, was insufficient to purify the sewage, and that where a slop-closet system is in vogue land filtration will have to be resorted to. In the part of his report dealing with infantile mortality Dr. Reid gives the following tables showing the effect of factory labour upon the death rates:—

Deaths in Children under One Year in Three Classes of Artisan Towns in Staffordshire.

	Class I. Many women engaged in work.	Class II. Fewer women engaged in work.	Class III. Practically no women en- gaged in work.
Ten years, 1881-90 ...	195	166	152
Five years, 1889-93 ...	199	176	167

It will be seen that the figures in regard to the five years 1889-93 are on a par with those from 1881-90. It seems that only in a few of the district reports is the question of the sanitary supervision of dairies, cowsheds, and milkshops noticed, and we trust that Dr. Reid's remarks under this head will produce a good effect.

Gloucester County Sanitary District.—The Medical Officers of Health (Reports) Committee of this county council state that they have examined the reports relating to the several sanitary districts for the year 1893, and as a result they have issued nine small pages of printed matter thereon. We regret that we are unable to say much in favour of the report, as it treats only in the most superficial fashion of sanitation in the county. We learn, however, from it that there are still seven sanitary authorities "so retrograde" as to refuse to those under their care the advantages of notification. The several zymotic diseases other than small-pox are dismissed with but a few lines each, while one page is devoted to small-pox. All the authorities in the county are, we are told, alive to the importance of a pure water-supply, and we are glad to learn that the activity of the sanitary authorities increases year by year. Such important subjects as river pollution, the houses of the working classes, the control of the milk traffic, &c., are passed over in silence; and no serious attempt is made to analyse the vital statistics relative to the county.

Lanark County Sanitary District.—Dr. James McLintock's election as a member of the newly-formed Local Government Board of Scotland renders his third report to the Lanarkshire County Council, the last that he will make in his capacity as county medical officer of health, and he will in the future be in a position to forward in no small degree the necessary reforms of his district. Dealing with the housing of the working classes in the landward areas of Lanarkshire, Dr. McLintock is able to state that considerable progress has been made, particularly in miners' houses, since his last report, and that an experiment being made to house the miners in a new way, it seems, indeed, that the housing of the working classes has been improved.

McLintock expresses the opinion that the praiseworthy resolve of Glasgow to do its part towards the purification of the Clyde must lead in a short time to similar action on the part of other sanitary authorities. He considers that in many cases no very great outlay will be necessary, inasmuch as in his opinion the sewage can be disposed of over suitable land at a small cost. It seems, however, that in many instances extensive trade effluents will have to be dealt with. New water supplies are being rapidly provided in the county, more especially in the middle ward, and, as Dr. McLintock remarks, it may be expected that several severe outbreaks of enteric fever due to polluted drinking-water which occurred in 1893 will not recur. Dr. McLintock states, in advocating a new Public Health Act for Scotland, that the most pressing requirements are powers to frame and enforce building regulations, and to form special cleansing districts. There is contained in the report before us a paper by Dr. Macmartin Cameron on 'Twenty Years' Vital Statistics in Lanarkshire. This paper is lucidly written, and very considerable labour must have been expended in its compilation.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 4921 births and 3615 deaths were registered during the week ending Dec. 29th. The annual rate of mortality in these towns, which had declined in the preceding three weeks from 20.2 to 18.2 per 1000, further fell last week to 18.0. In London the rate was 17.2 per 1000, while it averaged 18.6 in the thirty-two provincial towns. The lowest rates in these towns were 6.5 in Croydon, 13.2 in Leicester, 13.6 in West Ham, 13.8 in Norwich, and 15.1 in Cardiff; the highest rates were 22.7 in Burnley, 23.0 in Sunderland, 23.3 in Brighton, 24.0 in Gateshead, and 26.2 in Preston. The 3615 deaths included 385 which were referred to the principal zymotic diseases, against 426 and 392 in the preceding three weeks; of these, 153 resulted from measles, 64 from diphtheria, 56 from "fever" (principally enteric), 51 from whooping-cough, 34 from scarlet fever, 23 from diarrhoea, and 4 from small-pox. No fatal case of any of these diseases occurred last week in Croydon; in the other towns they caused the lowest death-rates in Bristol, Halifax, Leicester, and Preston, and the highest rates in Portsmouth, Newcastle-upon-Tyne, Burnley, Leeds, and Gateshead. The greatest mortality from measles occurred in Burnley, Newcastle-upon-Tyne, Portsmouth, Leeds, and Gateshead; from whooping-cough in Norwich, Huddersfield, and Swansea; and from "fever" in Derby and Sunderland. The mortality from scarlet fever showed no marked excess in any of the large towns. The 64 deaths from diphtheria included 35 in London, 6 in Manchester, and 3 in Leicester. One fatal case of small-pox was registered in London, 1 in Birmingham, 1 in Liverpool, and 1 in Hull, but not one in any other of the thirty-three large towns. There were 16 cases of small-pox under treatment in the Metropolitan Hospitals on Saturday last, the 29th ult., against 33, 22, and 15 at the end of the preceding three weeks; 1 new case was admitted during the week, against 7, 3, and 0 in the preceding three weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital, which had been 2142, 2034, and 1931 at the end of the preceding three weeks, was 1890 on Saturday last; 116 new cases were admitted during the week, against 187 and 161 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 358 and 325 in the preceding two weeks, were 332 last week, and were as many as 305 below the corrected average. The causes of 75, or 2.1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Nottingham, Oldham, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Leicester, Salford, and Blackburn.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the thirty-two Scotch towns, which was 21.2 and 21.7 per 1000 in the preceding two weeks, was 21.0 last week.

the eight Scotch towns ranged from 13·7 in Leith and 17·2 in Edinburgh to 24·5 in Glasgow and 26·9 in Aberdeen. The 629 deaths in these towns included 41 which were referred to measles, 18 to whooping-cough, 12 to diarrhoea, 8 to scarlet fever, 4 to diphtheria, 2 to "fever," and 1 to small-pox. In all, 86 deaths resulted from these principal zymotic diseases, against 90 and 111 in the preceding two weeks. These 86 deaths were equal to an annual rate of 3·0 per 1000, which was 1·1 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 26, 32, and 54 in the preceding three weeks, declined again to 41 last week, of which 24 occurred in Glasgow, 9 in Aberdeen, and 4 in Edinburgh. The 18 deaths referred to whooping-cough showed a slight further increase upon the numbers recorded in recent weeks, and included 14 in Glasgow. The fatal cases of scarlet fever, which had declined from 12 to 9 in the preceding three weeks, further fell to 8 last week, of which 7 occurred in Glasgow. The deaths from diphtheria, which had been 7, 8, and 10 in the preceding three weeks, declined to 4 last week, and included 3 in Glasgow, where the 2 fatal cases of "fever" were also recorded. The death from small-pox was registered in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 157 and 142 in the preceding two weeks, further declined to 138 last week, and were 15 below the number in the corresponding week of last year. The causes of 52, or more than 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27·1 and 26·5 per 1000 in the preceding two weeks, further declined to 25·4 during the week ending Dec. 29th. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the city averaged 23·5 per 1000, against 18·6 in London and 19·6 in Edinburgh. The 170 deaths registered in Dublin during the week under notice showed a decline of 8 from the number in the preceding week, and included 21 which were referred to the principal zymotic diseases, against 18 and 22 in the preceding two weeks; of these, 10 resulted from small-pox, 3 from whooping-cough, 3 from "fever," 3 from diarrhoea, 2 from scarlet fever, and not one either from measles or diphtheria. These 21 deaths were equal to an annual rate of 3·1 per 1000, the zymotic death-rate during the same period being 1·8 in London and 1·7 in Edinburgh. The fatal cases of small-pox, which had been 5 and 6 in the preceding two weeks, further rose to 10 last week; during the thirteen weeks of the quarter ending on Saturday last no fewer than 51 deaths have been referred to this disease in Dublin. The fatal cases of whooping-cough, which had increased from 1 to 5 in the preceding three weeks, declined to 3 last week. The deaths referred to different forms of "fever," which had been 2, 4, and 7 in the preceding three weeks, declined again to 3 last week. The 170 deaths in Dublin included 22 of infants under one year of age and 55 of persons aged upwards of sixty years; the deaths of infants showed a marked decline, while those of elderly persons showed an increase upon the numbers recorded in recent weeks. Seven inquest cases and 6 deaths from violence were registered; and 70, or more than a third, of the deaths occurred in public institutions. The causes of 15, or nearly 9 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

The following officers have arrived from India on completion of a tour of service:—Surgeon-Lieutenant-Colonel Birrow, Surgeon-Major Jencken, and Surgeon-Captain Green. Surgeon-Major James has been appointed to Shorncliffe; Surgeon-Major Heffernan to Woolwich; Surgeon-Captain Rawnsley to Hounslow; and Surgeon-Captain Macdonald to Belfast. Surgeon-Captain Hayes has embarked for Malta in succession to Surgeon-Captain Forrest, transferred to half-pay. Surgeon-Lieutenant-Colonel Carter and Surgeon-Major Thiele have arrived in Malta; Surgeon-Captain Nannerley at the Straits Settlements; and Surgeon-Captain Marks at Barbadoes. The retired pay appointment

at Newcastle-on-Tyne has been conferred upon Surgeon-Lieutenant-Colonel Hoysted.

ARMY MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel William Henry Bant Clapp, M.D., is placed on retired pay.

INDIA AND THE INDIAN MEDICAL SERVICES.

The following appointments are announced:—Surgeon-Lieutenant-Colonel F. C. Barker, M.D., F.R.C.S. Irel., to resume Charge of his substantive appointment of Medical Officer to the Kathiawar Political Agency and in Charge of the West Hospital, Rajkot; Surgeon-Captain H. Herbert, F.R.C.S., to resume Charge of his substantive appointment as Civil Surgeon, Kaira. Surgeon-Captain J. L. T. Jones, M.B., on relief, to act as Civil Surgeon, Broach. The services of Surgeon-Lieutenant-Colonel A. S. Reid, M.B., I.M.S. (Bengal), Medical Officer, 2nd Battalion 4th Gurkha Regiment, Officiating Agency Surgeon in Baghelkhand, and Tutor to H.H. the Maharaja of Rewa, are replaced at the disposal of the Military Department. Surgeon-Lieutenant-Colonel Albert Baird Seaman is promoted to Brigade-Surgeon-Lieutenant-Colonel. Surgeon-Lieutenant-Colonel Joseph Wilson, M.D., I.M.S., retires from the service.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant-Colonel Cornelius S. Hall, having resigned his Volunteer appointment, ceases to be an officer of the Army Medical Reserve of Officers. Surgeon-Major James Creagh, to be Surgeon-Lieutenant-Colonel. The undermentioned Surgeon-Captains to be Surgeon-Majors: Samuel B. Mason; George Middlemiss, M.D.; Francis L. Stephenson, M.B.; William S. Symes. Surgeon-Lieutenant Walter K. Loveless to be Surgeon-Captain. Surgeon-Lieutenant Charles Carter Moxon, 2nd Volunteer Battalion, the York and Lancaster Regiment, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Royal Engineers: 2nd Lancashire (the St. Helens): Surgeon-Major E. F. Hall, M.D., to be Surgeon-Lieutenant-Colonel. *Rifle:* 3rd Volunteer Battalion, the Devonshire Regiment: William Langran, Gent., to be Surgeon-Lieutenant.

PRACTICAL THERAPEUTICS.

The experiment of distributing packets of quinine through the post-office for the use of the native population of India has proved so popular and successful in Bengal that the Bombay Government is arranging for the distribution of the drug in the Bombay Presidency. Packets of quinine will soon be procurable at all the district post-offices in the Presidency and in Sind. It is understood that the Surgeon-General and Postmaster-General of Bombay are engaged in settling the details for giving effect to the proposal. The natives of India appear to have a lively faith in the virtues of quinine for the cure of fever, and as a prophylactic remedy against malarial disease.

HORSES FOR MEDICAL OFFICERS.

Adverting to a paragraph under the heading of "The Services" in THE LANCET of Dec. 15th, 1894, regarding a provision in the last edition of the Queen's Regulations for medical officers being mounted when with an infantry unit, an esteemed army correspondent refers us to the Army Orders for November, 1894 (which are a reissue of this portion of the Queen's Regulations), in which this important addition is omitted. The privilege is, as heretofore, restricted to medical officers when serving with a mounted unit, and matters consequently stand where they were.

SIR WILLIAM LOCKHART'S FORCE.

Among the appointments which have been made to the staff of the expeditionary force under General Sir William Lockhart we notice the names of Brigade-Surgeon-Lieutenant-Colonel Spencer as P.M.O. with the headquarters staff; Brigade-Surgeon-Lieutenant-Colonel Davies as Senior Medical Officer of the Wano Brigade; and Surgeon-Major Shearer as Senior Medical Officer of the Jhandola Brigade.

RETIREMENTS AND VACANCIES IN 1895.

Among the retirements and vacancies in the medical staff in the course of the present year there will, we believe, be four in the rank of surgeon-major-general, one in that of surgeon-colonel, and three in the rank of brigade-surgeon-lieutenant-colonel.

The Government of India has sanctioned the introduction of Surgeon-Major Ranking's "Guide to Hindustani" as a text-book for general use in regimental schools.

"Audi alteram partem."

"CHILD MORTALITY IN ENGLAND."

To the Editors of THE LANCET.

SIRS,—You have honoured me with a second leading article in THE LANCET of Dec. 22nd, and there is much in it with which I agree; yet I cannot but regard your dealing with my argument as incomplete and likely to mislead, which, I am sure, is far from your intention. You refer to the labours of that giant statistician, the late Dr. Wm. Farr, as if he were adverse to my view. I was the first to read a certain presentation copy of Mr. Noel Humphreys' excellent compendium of his works, and my impression is that Dr. Wm. Farr would have encouraged the use of coefficients like mine as the best means of setting forth the relative mortality of the several age groups. I did not arrive at these coefficients in the way you suppose. Had I done so the errors would have been prodigious though concealed. From 1881 to 1891 the estimated population of the age group 0 to 5 went more and more widely wrong in the annual reports and summaries of the Registrar-General owing to circumstances over which he had no control, so that in 1890 there was an error in excess of about 78,000 as regards the population of the said group in London alone. No wonder the death-rate of the group seemed to decline rapidly. Coefficients of incidence are for the purpose of comparing the death-rates of the several age groups with the average for the time being. The exact relation of each group death-rate to the average being given year by year any variation can be noted. Having the average and the coefficient we easily obtain the group death-rate as their product. But I contend that it is advantageous to be able on occasion to study the relative proportion of the group death-rate to the average without having that group death-rate or even the average itself as a disturbing element always before our eyes. We may place ourselves in a fools' paradise if we look at a declining group death-rate only. What I have found is that from 1876 onwards there has been in regard to the age group 0 to 5 a continual increase in the coefficient of incidence of mortality, showing that this group has had an ever-increasing share of the deaths that occur. You yourself admit that "the rate of decrease of child mortality has not been equal to the rate of decrease of mortality at the later age periods." This way of putting it disturbs the conscience of the nation less; but there must be a cause for the difference you concede, and I ask, What can that cause be? You suggest that if some means of eradicating cancer and phthisis were discovered I could not be grieved, and yet as these are destructive to the later age groups the improvement would make the incidence of mortality upon the younger group all the greater in comparison. So far from denying this, I accept it as strengthening my position. If A and B are running level in a race it makes no difference to the result whether A run slower or B run faster—B wins. But in the case before us the younger age group lags far behind, and that is why special attention should be paid to this group first. It is the turn of the children this time. Let us try and discover some means of removing Death's icy hand from them.

I was not, as you suppose, ignorant of the fact that, if the present excessive rate of mortality among children under the age of five years could be reduced to a third of its present figure, the coefficient for this age period would decline much less. It would become about five-elevenths of what it now is, supposing all else to remain the same. In order to reduce the coefficient to unity the death-rate of children under five years of age would have to decline to three-fourteenths of its present proportions, for the death-rate of this unfortunate group is at present nearly five times as great as the average death-rate of the other groups. I am, Sirs, yours faithfully,

diminishing in numbers at the wrong end (those least fit multiplying pretty much as heretofore), and that the actual death-rate of infants under one year of age was increasing, but showed that five of the seven principal zymotic diseases were increasingly fatal to the group 0 to 5 as a whole when compared with the later groups. Thus, in London during the eighteen years 1876-93 the coefficients of incidence of mortality upon this group ran up as follows: scarlet fever from 5.044 to 5.660, diphtheria from 4.618 to 5.723, measles from 7.186 to 7.952, whooping-cough from 7.401 to 8.148, and diarrhoea from 6.849 to 7.505, and the ascent was in each case by fairly regular gradation. Now you cannot account for this fivefold increase by any supposed relief to the other groups as regards cancer, phthisis, &c.; and yet there must be some cause, or combination of causes, to account for it. The increase has occurred in the coefficient irrespectively of the direction in which the average death-rate from the disease has moved; in some this has declined, in others (notably diphtheria) it has risen. You must admit, taking each of these five diseases by itself, that the age group 0 to 5 is not only less able to resist the onslaught than are the other groups (that is patent from the magnitude of the coefficients given above), but that it has become in comparison less and less able since each coefficient has increased. Year by year it has had a greater share of the deaths that occur from each of these five zymotic diseases. Can you account for this on any other hypothesis than that which presented itself to me? Perhaps you will copy your astute contemporary and declare that the result would have been different if the years had been transposed. Such statements win my admiration.

I am, Sirs, your obedient servant,
Kingston-on-Thames, Dec. 27th, 1894.

D. BIDDLE.

CANCELLING OF DEGREES.

To the Editors of THE LANCET.

SIRS,—Referring to the report in THE LANCET of Dec. 1st, 1894, of the proceedings of the General Medical Council, it seems a pity that so much of the time of the Council should have been taken up in discussing the question of the degradation of university graduates, when a little inquiry would have elicited the fact that universities were not so neglectful of their duty in the matter as has been supposed. As regards the University of Aberdeen the subject has recently been brought before the Scottish Universities Commissioners in a memorial addressed to them by the Senators, the initiative having been taken by that body, and not by the University Court, as might perhaps be inferred from your report. If the Commissioners regard the subject as within the scope of their commission, it is to be hoped that they will issue an ordinance prescribing the circumstances and mode in which an offending graduate may be deprived of his degree. If not, it will be necessary to have the sanction of Parliament by legislative enactment. In addition to the difficulties which were spoken of at the discussion in the Council there has also been suggested this one—that as the medical degree confers a Parliamentary franchise, the cancelling of it would result in disfranchisement. But this should be no real difficulty. If some of our politicians have their way all universities will shortly be deprived of their Parliamentary privileges; and, even were it otherwise, the penalty of disfranchisement is not too heavy to pay for such "infamous conduct" as would lead to the removal of a graduate's name from the roll of his university. I am, Sirs, yours faithfully,

Aberdeen, Dec. 17th, 1894.

DAVID W. FINLAY.

"ASSOCIATION OF QUALIFIED ASSISTANTS, JUNIOR MEDICAL OFFICERS, AND LOCUM TENENS."

To the Editors of THE LANCET.

SIRS,—I shall be pleased to receive the names of gentlemen who are favourable to the formation of such a society, stating their views on the subject, also giving their qualifications and addresses, so that I may be enabled to ascertain whether such an association as the above would meet with the approval and cooperation of a sufficient number of qualified medical men. I am, Sirs, yours faithfully,

bearings. Personally I think such an association, rightly managed, might do an immense amount of good and useful work, and would be the most powerful instrument in detecting, and ultimately eradicating, the shameful practice of employing unqualified men as medical assistants, a practice unjust to qualified men, degrading to the best interests of our noble profession (should be), and an imposition on the public at large—I am, Sirs, your obedient servant.

T. HOWARD BROCKLEHURST, M.R.C.S. Eng., &c.

Lichester-villa, Westham, Weymouth, Dec. 26th, 1894.

* * We comment on this proposal in another column, but may note here that the heading of this letter recalls a well-known *rexata questio*. An authoritative statement from a philologist as to the proper and appropriate plural of "*locum tenens*" (used in its technical sense) would be welcome to those who appreciate the "purity" of language.—ED. L.

THE CONTAGION OF CRIME.

To the Editors of THE LANCET.

SIRS—It is not a little remarkable that two lads with excellent moral antecedents should be all but simultaneously arraigned before the criminal courts for the perpetration of heinous crimes. In few quarters should such an occurrence be less expected. Scrutinising the painful incidents more closely they seem to me to involve considerations of not less moment for the medical jurist than for a psychologist and legislator. That crime is spread by imitation and human nature brutalised by familiarity with it, are propositions accepted by the most competent criminologists. This is amply demonstrated, among many others, by Dr. Paul Aubrey in his distressing work "*La Contagion du Meurtre*," a second volume of which appears this year. The question may then be pertinently asked, even while one of the cases is still *sub judice*. To what extent have these unhappy young men, and doubtless many others, not been the victims of a licentious and pernicious press? In the compass of a brief letter it is impossible and perhaps inexpedient to do more than glance at the striking examples of criminal contagion given by Aubrey under the heads of "*Contagion by the Family*," "*Contagion by Community of Life*," "*Contagion by the Spectacle of Public Executions*," "*Contagion by the Press*," "*Contagion by some Special Modes of Murder*," &c. On a case with which the people of this country are too familiar, that of "*Jack the Ripper*," Aubrey deals at some length as illustrative of criminal contagion, and the potency of press publicity as one of its etiological factors. Many similar examples of every manner of crime might be cited, but this one illustrates them all in their various gruesome aspects. It is not without justice that the author sneers at the affected moral superiority of the "*English*" and the "*ignominious*" condition of the streets of London when holding the record for criminal mutilation. The Whitechapel brutalities and their consequences are as follow. On July 17th, 1887, Alice Mackenzie, forty years of age, was found with her throat cut and her abdomen incised up to the umbilicus. On April 3rd, 1888, Emma Smith was violated and killed by a band of men comprising "*Jack the Ripper*." Martha Tabran on Aug. 7th received thirty-nine stabs. Ann Nichols, about Sept. 4th, had her head separated from the trunk and the abdominal cavity opened throughout its entire length. On Sept. 8th Annie Chapman had her head half severed from her body, her abdomen opened, her intestines drawn out of the body, and her heart and liver placed under her head for a pillow. Jane Mary Kelly, aged twenty-two years, had her head separated from the trunk, her nose and ears cut off, and her breasts removed. On Sept. 30th Elidowes was assassinated and the body mutilated. On the same date Elizabeth Stride had her throat cut, but there were no mutilations. On Nov. 11th the liver and intestines of a female were torn out and placed on a table and the limbs carved by knife cuts. On Dec. 26th a female was strangled with a cord. On Sept. 10th, 1889, a female body was found with the head and arms wanting; it presented the usual mutilations and was enveloped in a sack. In February, 1892, Frances Coleman, twenty-five years of age, had her throat cut; and just the other day a mere boy in America "*ripped*" two children of about the same age. After the London atrocities similar crimes were perpetrated all over the world. At Bradford an infant was found eviscerated in 1886 and the extremities and ears strewn round the trunk.

In 1889 two murders with mutilation took place in Hamburg. In 1890 in Moscow the mutilated body of a Sister of Charity was found in a sack. At Berne in December of the same year "*Jack the Ripper*" again appeared. In 1891 at Liverpool an infant was cut up in morsels and thrown into one of the docks. At Brussels in July, 1891, an infant aged thirteen months was found eviscerated. In October of the same year at Berlin the eviscerated body of a female was found. Three days afterwards Vanbourg slew and mutilated Boutry in the Rue de Charonne; in November, at Madrid, a female body was found eviscerated and mutilated. In the month of July, 1892, Madame Leblau was cut into particles and thrown into the Meuse at Tilly-sur-Meuse. In October, in the Rue Bokaris, a body was found cut in particles. Southampton, Glasgow, the United States, and Honduras contributed to this ghastly roll.¹ Can any sane person believe that a fractional portion of these atrocities were the work of one individual? Is it not morally certain that we have here the influence of criminal contagion, and that its inception is chargeable to the apotheosis by the public press of crime and criminals? This has been fully recognised by the Congrès International contre la Littérature Immorale et le Danger de la Publicité des Faits Criminels, held at Lausanne in September of last year; and it is high time an elevated patriotism recognised it here. Thousands—aye, millions—of young people are corrupted by the daily press—are made acquainted with crimes of which but for it they would ever remain in blissful ignorance. It is almost impossible to take a daily paper into the domestic circle without the risk of moral contamination. No sooner is a foul murder, a "*judicial murder*" (the blot *par excellence* of Britain among civilised nations), a detestable incest, or a distressing suicide perpetrated at Land's End then it is flashed to John o' Groats. Columns of newspapers are filled with revolting details, broken up under myriad headings cunningly devised to excite and impress the most morbid pruriency. What conceivable good except a few more filthy coppers to the exchequer of the newspapers is thus accomplished it is hard to conceive; what an amount of crime is thus propagated it is not difficult to comprehend. It is surely the function of a patriotic and philanthropic press to relegate to the background and to obscure the distressing features of human nature and to hold up for imitation its nobler and diviner aspects. I venture, then, to express the conviction that if the low periodical literature—of the metropolis in particular—were strangled by the firm hand of an enlightened and a benevolent legislative enactment, if public moral influence were so brought to bear on all the newspapers in the country as to make them feel that their interests lay (to make them ashamed were a Quixotic attempt) in a pure press, crime of all kinds would *pari passu* disappear, and a condition of society would emerge more in consonance with the blatant philanthropic and religious pretensions of a distracted nation.

I am, Sirs, yours truly,

D. CAMPBELL BLACK, M.D. Glasg.,

Professor of Physiology in Anderson's College
Glasgow, Dec. 25th, 1894. Medical School.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Owens College.

MANCHESTER is proud of its ancient Grammar School, which links it with the past. It is perhaps equally proud of Owens College, its one educational institution of the highest and most advanced type, but the product of the last fifty years. It delights in its purely local origin, for John Owens was a Manchester merchant, and in the fact that its growth and vigorous strength are due to the fostering care of Manchester citizens. On May 31st, 1845, John Owens signed his will, leaving over £52,000 to relatives, friends, charities, and servants, and the residue "for providing or aiding the means of instructing and improving young persons of the male sex (being of an age not less than fourteen years) in such branches of learning and science as now and may be hereafter usually taught in the English universities," coupled, however, with this fundamental condition that no one connected with the proposed institution should be required to submit to any test whatever as to

¹ Vide Cone: Crime et Suicide. Paris, 1891.

his religious opinions, and that nothing should be introduced in the education or instruction "reasonably offensive to the conscience of any student or of his relations, guardians, or friends under whose immediate care he shall be." He died the next year at the age of fifty-five. He was a bachelor, of somewhat delicate health, who had led a quiet and almost secluded life, had taken little or no part in public affairs, and was, therefore, but little known to his fellow townspeople. He had been a manufacturer and shipper, was successful in business, as was also his father before him. Comparatively little is known of his personal life, but evidence exists to show his interest in education, and that he thought much on the collegiate system he hoped to establish in Manchester. The residue of his estate realised £96,654 11s. 6d. None of the money, however, could be used for the purchase of property or for building. An escape from this difficulty was provided by Mr. George Faulkner, the chairman of the trustees, and an old friend of Mr. Owens, for he bought the late Richard Cobden's house in Quay-street, giving £4500 for it, and let it to the College until 1854, when he presented it to the trustees. The premises were extended from time to time at a cost of about £10,000. The institution grew and developed and the students gradually increased in number, so that at length a scheme for extension on a large scale was almost forced on the trustees. But before these trying days had been passed—and, indeed, for many years—the new College had a hard struggle for existence. The first complete session was opened in October, 1851, and the ordinary students numbered sixty-two; but in 1856–57 they had dwindled to thirty-three, and in 1860–61 were only sixty-nine. So far there was no medical department, though the Manchester Medical School was one of the most important in the provinces. It was founded by the late Mr. Thos. Turner in 1824, and in 1836 the prefix "Royal" was allowed on account of its "excellent equipment." In 1856 negotiations with the College took place on the question of amalgamation, but they were unsuccessful, the College authorities thinking the terms proposed too one-sided; so the matter rested for several years. In the meantime the position of the College gradually improved, and in 1867 the extension scheme was set on foot, with the result that the sum of £211,152 12s. 4d. was raised. Since then many large gifts and benefactions have been received for the endowment of special departments, and the College has had many valuable gifts of books, philosophical instruments, and other teaching appliances. The amalgamation of the school and College took place in 1872, and the buildings for the medical department were opened in 1874. The College in Oxford-road is now an extensive collection of buildings, and will be still further enlarged as time goes on. The important additions recently opened by the Duke of Devonshire have already been noticed in the columns of THE LANCET,¹ and it may be said that as regards convenience of arrangement, wealth of scientific appliances, and opportunities for research in all directions pertaining to medicine Owens College is well abreast of all existing schools of medicine. Clinical instruction is chiefly given at the Royal Infirmary, though other special hospitals are associated in this work. The distance between the College and Infirmary has sometimes been thought a drawback, but practically it is not found to be so. It is a little over a mile, and the break between close work at one place and then at the other is a relief and refreshment, and for those who do not care to walk there are tramcars which go from door to door, and cover the distance for a penny. The Infirmary and the College now work in thorough harmony, but for many years more or less friction existed. No doubt there were faults on each side. The Royal Infirmary was venerable, and its reputation high, before the College came into being, and instead of overlooking or excusing what seemed to be a somewhat supercilious assumption of superiority—natural, perhaps, to a young college recently manned by professors imported mainly from our old universities or from beyond the Tweed to bring light into Lancashire—the older institution was too sensitive and a state of chronic irritation was set up. This unfortunate feeling was not lessened by the ill-judged appointment to the chair of Surgery of a gentleman who, though an Englishman, hailed from Edinburgh. He was liked personally, and the feeling towards him was one of kindness and commiseration; but though he was well informed and had done some literary work

he did not possess the qualifications required for admission to the Infirmary staff, so that he could only give clinical teaching by joining the Ancoats Hospital. After a few years this gentleman resigned, and a well-known member of the Infirmary staff is now the Professor of Surgery. All this, however, is a story of the past—the College has outgrown its youthful vanities, the Infirmary has recovered its equanimity, and the relations between the two are better understood. The establishment of the Victoria University, a teaching and examining body whose degrees have already acquired prestige and value, must have a stimulating effect on medical education in the north of England; while the three colleges of Leeds, Liverpool, and Manchester, already affiliated, will exercise a generous rivalry, tending to maintain in each a high standard of efficiency.

Lead Poisoning.

A case of discreditable carelessness—to use a mild term—as to human life was brought to light the other week at an inquest on a girl who died from lead poisoning. She had been employed by a firm of dyers in Newton Heath in "noddling" yarns dyed orange or yellow, presumably by chromate of lead, the handling of which is notoriously dangerous. Three years ago two girls at the same works died from the same cause. Out of thirty-six girls employed the manager admitted that he only knew of three who had never been away ill from lead poisoning. The coroner said it was a most outrageous thing that girls should be allowed to commit suicide merely to supply yellow goods to foreign markets, and the jury returned a verdict to the effect that the deceased had died from lead poisoning caused by the firm neglecting to carry out the promises made by it three years ago.

The Smoke Nuisance.

The war between the smoke producers and those who object to their air passages being made receptacles for particles of carbon, each carrying its little cargo of empyreumatic filth and sulphurous acid or other noxious gas, shows signs of revival. A deputation from the Manchester Chamber of Commerce, representing chemical, iron, and dyeing industries, and brick, tile, and terracotta manufacturers, waited the other day on a committee of the corporation in reference to prosecutions for excessive smoke production. The matter is to be formally considered by the sanitary committee. The arguments used came from the pockets rather than from the minds of the deputation, and were of the usual stock character. Our air is sufficiently polluted as it is, and one wonders what would be the state of things if manufacturers and the users of dangerous lead compounds had all their own way. It will be interesting to see how the sanitary committee deals with this confessedly difficult matter.

Jan. 1st.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Christmas and the New Year.

NOTWITHSTANDING the great depression of trade and commerce which has been prevalent here for so long, it has not prevented the usual flow of charity among the poor at this season. More than the usual number of "hot-pots" were distributed, providing a good dinner for a large number of families. In addition to this a large number of aged persons and children have been treated to substantial meals at St. George's Hall. It is very gratifying to add that the number of persons brought before the magistrates on New Year's Day was only half that of last year, while the city was altogether free from the shocking crimes which disgraced it last year on these festive days. The citizens have evidently found that it is quite possible to be both merry and wise.

Small-pox and Revaccination.

The recent scare caused by the importation of a few cases of small-pox has had an excellent effect in inducing many persons to undergo revaccination who otherwise would not have done so. Liverpool is so peculiarly situated that the importation of small-pox, as well as of other diseases, by sea or land is a contingency which may occur at any moment. For this reason it is of paramount importance that not only

¹ THE LANCET, Nov. 10th, 1894.

should primary vaccination continue to be strictly enforced, but revaccination should be urged upon all persons before the attainment of adult life. It is astonishing to those who have made it their business to inquire to find that while some few persons have been vaccinated twice, thrice, or even four times, the greater number by far have never been vaccinated since infancy. Knowing as we do the almost absolute protection of a second vaccination, this state of things ought not to be. Without resorting to compulsion, much may be done by example and influence.

The Atmosphere of the Police Court.

Our stipendiary magistrate said lately in allusion to the polluted state of the atmosphere in the court over which he presides that it was the vilest hole in the city, a remark which was endorsed by the assistant prosecuting solicitor. It has now become a very old grievance, and as it must in the very nature of things become worse instead of better if not remedied, it is greatly to be hoped that the new year will see something done to rectify what is really a grievous scandal.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Edinburgh in 1894.

WHILE nothing of sensational interest has stirred medical Edinburgh during the past year a good deal has happened which has more than a merely passing interest. Some changes are the beginning of a future, even the possibilities of which can only be matters of surmise and speculation. To begin at the beginning of things it may safely be assumed that the number of medical students in Edinburgh has diminished; at the University this has certainly been the case, and it is almost equally certain that the same may be said of the number of purely extra-mural students, although this latter point is more uncertain, as until within the last year or two there was no attempt to ascertain numbers by any conjoint system of registration. The mere falling off in numbers is not in itself an evil, for all who knew the Edinburgh School saw and felt that it was terribly weighted by its numbers. Only in a great school, where teaching has evolved into an art, and where so much energy, time, and ability are lavished by a large body of teachers upon it, could matters have gone on as satisfactorily as they have done and could results have been as good. It is the character and quality of the teaching which have continued to attract students from all parts of the world, and which impress students who come to Edinburgh after experience of other schools. The preceding generation of teachers in Edinburgh contained men of outstanding eminence and world-wide fame, who by their individual qualities attracted students to the school. Now, it is not so much this as the character of the teaching which continues to attract. The teaching has attained its present standard through the impetus given to it by competition. The extra-mural school has been a strong, vigorous, and robust rival to the University, and has kept it more awake to the interests and needs of students than would otherwise have been the case, while the professoriate has also been kept more active. In the extra-mural school itself the competition of several lecturers on every subject has been amply sufficient to stimulate men to do their best for the students, and to endeavour to attract them to their prelections. While this has been good in its main effects, the system must inevitably have an undesirable side. The pecuniary motive has not been confined to the extra-mural school—the University professoriate has felt it and has been stimulated by it. It is difficult to estimate accurately the exact influence of it; with some men it has assuredly been an impelling influence, while with others it has almost as certainly not been felt as a motive in their work. The changes brought about by the Universities Commission will clear up this question. The individual student is no longer the representative of so many additional guineas to his professor, for the professors are now paid out of a central fee fund, and some of them have made fixed terms with the University Court on an average of preceding years, an average which in some cases has already fallen. The effect will be the complete elimination of the pecuniary motive so far as the individual professor is concerned, and ultimately the filling of professorial chairs by men whose work will be

determined by purely scientific considerations. That this is desirable and the ideal to be aimed at there can be no question. Meanwhile during the period of transition and the occupancy of chairs by their present occupants the University finances are certain to suffer heavily, and we are likely to hear a good deal on this point in the next few years.

The diminution in the number of students is mainly to be attributed to the altered regulations regarding the preliminary or entrance examination made by the Commission. The standard is a new one, and neither schools, tutors, nor candidates know yet what it is. The cry was to raise it, but the result has been so disastrous to the candidates that already influential voices have been raised against the results, if not the standard. Probably the mistake lies in the standard having been too suddenly and abruptly changed. The past year has been the date of another important departure on the side of the University. The Commission put it within the power of the University Court to admit women to the degree in medicine, while at the same time permitting them to make arrangements for their instruction outside the walls of the University. The Court, taking advantage of this, has recognised the two medical schools for women in Edinburgh as providing instruction which will be accepted by the University for examination and graduation. That this will have an important influence upon female medical education in Edinburgh is inevitable, and will doubtless encourage and strengthen it. What the ultimate issue will be, and what the relations of the University may be to it in the future, will depend probably upon its success; meanwhile the tendency and the feeling are, on the whole, against mixed classes, and at present the University could hardly take the women inside its walls on any other terms, and these terms would be too unpopular for the University to adopt. In the extra-mural school the most notable incident has been the opening of a new set of lecture rooms in Bristo-place, which are being run with considerable vigour and perhaps even a certain aggressiveness, and threaten to be a not inconsiderable rival to some of the older places. In the Royal Infirmary matters have gone on quietly and smoothly. The new superintendent is an economist, and has succeeded in restraining expenditure. In ward work abdominal surgery and brain surgery have been prominent, and if there is a long death-roll there have also been brilliant and encouraging successes. At the medical societies there has been some increased activity, and the Medico-Chirurgical Society has during the past two years been unusually active, and has had important discussions on subjects of special interest to the profession at the time they took place. As regards the public health of the city, the year has been characterised by a considerable epidemic of small-pox, which has taxed the resources of the Public Health Department and has demonstrated afresh the value of vaccination to the community. Amongst other zymotic diseases scarlet fever and measles have been epidemic in certain localities. The Royal College of Physicians has made arrangements for the preparation of antitoxin for the treatment of diphtheria, the difficulty of obtaining a sufficient supply of serum being the reason for this novel departure. In the latter part of the year the new buildings for the reception of private patients at the Morningside Royal Asylum were opened, and represent the most forward and ideal arrangements for the lodgment and care of the insane that the century has produced. In this department of medicine the retirement of Sir Arthur Mitchell from the Senior Commissionership in Lunacy dates from the end of the year; and the appointment of a successor is awaited with some anxiety, as it is felt that considerations largely of a political nature may unduly influence the election. The most noteworthy contributions to the more permanent form of medical literature have been Dr. Balfour's "Senile Heart" and Dr. Wyllie's "Disorders of Speech." The former may fairly be considered as its author's masterpiece. He has been for a quarter of a century regarded as an authority on cardiac affections, and this new book will not lessen his reputation. It bears traces of more care and labour devoted to its preparation than characterised his earlier work. It reads like a classic of the earlier part of the century, and while possessing the excellences of these is not devoid of their faults. From the standpoint of modern pathology, many points could be adversely criticised; but it contains much shrewd observation and advice. Dr. Wyllie's work is full of interest and is characterised by the power of intellect, the wealth of idea, and

the faculty of combining facts which those who know Dr. Wyllie recognise him as possessing in quite an exceptional measure, and make him one of the strongest personalities in the Royal Infirmary and the School of Medicine. Two new hospitals have been added during the year to the medical charities in the city—namely, the Victoria Hospital for Consumption and the Deaconesses' Hospital.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Small-pox in Dublin.

THE small-pox epidemic appears to be gaining ground, more especially on the south side of the city, and some of the suburbs are not exempt from the disease; during the week ending Dec. 22nd 113 cases were admitted to hospital, and the number under treatment at the close of that week amounted to 131, exclusive of 126 convalescent patients in the South Dublin Union Small-pox Hospital, Kilmaham. At a recent meeting of the guardians of the North Dublin Union a sealed order was received from the Local Government Board declaring, in view of the threatened small-pox epidemic, that their union should provide such medical aid, nurses, and accommodation as might be requisite for all persons affected by, or threatened with, small-pox, and that they should provide a joint hospital with the South Union, or a separate hospital. Mr. Stafford, Local Government Board inspector, who was present, said that in his opinion the sealed order brought them face to face with rather a serious state of affairs; for they had not yet made any arrangements themselves for treating small-pox patients, and the order threw on them the responsibility of not only making arrangements for the sick poor suffering from small-pox, but for the whole of the inhabitants of the North Dublin Union. The responsibility was rather a large one, and Mr. Stafford was afraid the guardians had not made sufficient provisions for it. He thought they would have to look out for a site for a convalescent hospital for small-pox patients. After some discussion as to possible sites it was agreed that a committee should confer with Mr. Stafford on the subject. It may be mentioned that the Hardwicke Hospital have twenty-six beds always at the disposal of the city for small-pox; but as the hospital authorities have been requested to accommodate more they have offered to place the whole hospital at the disposal of the citizens for small-pox cases, and have withdrawn all their nurses from private cases, and so soon as arrangements as to expenses have been made with the guardians of the North Dublin Union they will admit small-pox patients to all available beds in the hospital. The present epidemic shows the neglect of vaccination that existed among the poorer classes in Dublin, and the absolute necessity for revaccination.

Lunatics in Workhouses.

The Local Government Board have issued a circular on the admission and treatment of lunatics in workhouses in Ireland. The Board state that under existing laws for the relief of the destitute poor the guardians have no power to detain the insane in workhouses. In practice, however, they are detained because the district asylums are usually so overcrowded that applications for admission under the forms prescribed by the Privy Council rules cannot in many cases receive attention; but the fact ought not to be lost sight of that in all cases of alleged unsoundness of mind unaccompanied by destitution a workhouse is not the place for the reception, treatment, or custody of the insane. From a legal point of view the guardians are under no obligation to receive lunatics except when admitted as destitute persons or when discharged from an asylum for transfer to a workhouse, under the provisions of Section 2 of the Lunatic Asylums (Ireland) Act of 1875 (38 and 39 Vic., cap. 67). With reference to persons who have been admitted to a workhouse as destitute and who on admission, or at a subsequent period, are found to be insane, the Local Government Board have always held that if their insanity is of such a character as to call for the use of mechanical restraint immediate steps should be taken to apply for their admission to a properly equipped lunatic asylum.

Eye, Ear, and Throat Hospital, Cork.

The late bazaar, styled "Donnybrook Fair," held for the

purpose of building a new Ophthalmic Institution in Cork, has succeeded beyond the expectations of its promoters, the handsome sum of £4000 having been obtained for the required purpose. This sum, added to the amount previously subscribed, makes a total of £7000. Lady Arnott, who originated the collection of subscriptions and the bazaar, obtained at her stall in the bazaar the large sum of £557.

Presentations.

Mr. J. J. Murphy of Dublin, on the occasion of his recent marriage, has been presented with a purse of sovereigns, and a fruit service and star set with brilliants for Mrs. Murphy.—Mr. Alexander Gordon of Rathmines was last week the chief guest at a complimentary dinner given on his recovery from a severe illness, and was presented with a gold shield pendant. A valuable gold bracelet with diamond settings was also presented to Mrs. Gordon.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Ganglion.

THE means usually resorted to—prolonged pressure, forcible rupture, subcutaneous puncture, seton—for the cure of these troublesome cysts do not always prove satisfactory, the severer methods of treatment being frequently objected to by the patient. Professor Duplay of Paris has cured fifteen cases by having recourse to the classical treatment of hydrocele with iodine injections.¹ The skin over the ganglion having been carefully disinfected, a Pravaz's hypodermic syringe is sterilised and filled with the tincture of iodine of the French codex. The needle is plunged into the most bulging part of the cyst until its point reaches its centre, care having been taken by previous displacement of the skin to secure non-correspondence of the skin and cyst punctures when the cutaneous covering is allowed to resume its natural position. From five to ten drops (average, six or eight) of the tincture are slowly introduced into the cyst, the pressure necessary being often great when the ganglion is tense. The needle is then quickly withdrawn and the displaced skin allowed to retract. A little gentle massage of the tumour is practised, a pad of aseptic wool is placed over the spot, and the joint is immobilised and subjected to pressure by means of several layers of wool and a bandage applied. The injection provokes some pain, irradiating in the case of wrist ganglia to the forearm and hand. This pain may last for a couple of days, when it generally disappears. When, on the third or fourth day, the dressing is removed the cyst is found to have already shrunk. The part, although tender to the touch, is not inflamed. The compressive dressing is renewed, and in five or six days the ganglion has disappeared. Should it still persist—one injection generally suffices—the operation may be renewed. Most of Professor Duplay's cases were treated several months ago, and no relapse has been noted.

The Restoration of the Nose by Martin's Method.

M. Martin of Lyons has invented a metallic substitute for the nasal bones, the absence of which is so often the cause of failure in the Tagliacotian operation. To this bridge is fixed a metallic tripod, whose office it is to support the flaps. Unfortunately the excellent result at first procured is finally discounted by the suppuration excited by the tripod, which is then eliminated. M. Chaput² avoids this *contretemps* by plunging the extremities of the tripod into holes bored in the surrounding bone. This is done in order to place the ends beyond the reach of suppuration germs. In this way the apparatus is tolerated for ten or fifteen months without inconvenience. M. Chaput employs platinum for the fashioning of the tripod support, but he opines that the less costly silver-gilt would do as well. Of two cases operated on by him one was quite satisfactory, the restored organ being aesthetically a good imitation. The second case was a comparative failure, the tripod having been made too large.

Laryngotomy as a Diagnostic Measure in Epithelioma.

M. Manoury of Chartres³ had recently under treatment a man aged thirty-eight, whom he found at his first visit in a state of asphyxia. Tracheotomy was at once performed.

¹ Archives Générales de Médecine, December, 1894.

² Société de Chirurgie, Dec. 26th, 1894.

³ Ibid.

Epithelioma of the larynx was diagnosed, but confirmatory evidence was, under the circumstances, unobtainable. Median laryngotomy was accordingly performed, and the existence and extent of the (epitheliomatous) growth having been thus discovered the entire larynx was, *stance tenante*, removed by Perrier's method. On the thirteenth day the patient was able to drink, and on the sixteenth day he ate as usual. The operation was performed on Nov. 3rd, 1894, and the man was presented to the society quite well. M. Quénu approves of the preliminary laryngotomy in these doubtful cases, and as lately as a week ago he had recourse to the same proceeding.

Antitoxin.

On and after to-day, Jan. 1st, 1895, applications made to the Pasteur Institute in the name of a physician or of the family by the mayor, prefect, sub-prefect, and *bureaux d'hygiène* of any part of France will result in the immediate despatch of a tube of antitoxic serum. This arrangement is only provisional, it being hoped that depôts of antitoxin will at no distant date be established in the provinces. It will thus be seen that M. Roux and his assistants have not been idle. Indeed, both the Institute authorities and the public have worked with a will, the latter having, through the *Figaro* and by means of gifts made directly to the Institute, contributed up to Dec. 31st, 1894, no less a sum than 611,000 francs (£24,440). This does not include 100,000 francs (£4000) just voted by the Chambers, and which will doubtless become an annual subsidy. On Oct. 12th the Pasteur Institute possessed for immunising purposes a stud of twenty horses. This stud has now been increased to 136 horses, a total that will probably be ultimately increased to the maximum of 150. Fifteen of these animals are at the State Veterinary School of Alfort, where they are kept under close observation (with regard to pulse, temperature, &c.) by Professor Nocard and his pupils. Forty-two horses are located in the old abattoirs of Grenoble placed at M. Roux's disposal by the Municipal Council of Paris. Of these, twenty are kept by the municipality at a cost of 20,000 francs (£800) a year for the benefit of the Paris hospitals and poor. At Villeneuve-l'Étang—a property ceded by the State to M. Pasteur in 1886—there are seventy-nine horses cared for by a capable veterinary surgeon and his staff. While the regulation six litres of blood (yielding about half that quantity of serum) are being drawn from the jugular vein the animal's attention is easily distracted by a handful of carrots, which he munches contentedly. On the day following the phlebotomy immunisation is recommenced and continued for five days. A rest of fifteen days follows, and then another bleeding may be practised. That the animals flourish under this régime of good feeding and periodical bleedings is proved by the presence in good health at Alfort of a sturdy Brittany pony which has hitherto supplied no less than 420 litres of blood. Professor Behring spent a few days of last week in Paris in order to visit Dr. Roux and inspected the arrangements now being made to combat diphtheria in this city. During his stay he visited Villeneuve-l'Étang.

Jan. 1st.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Antitoxin Treatment of Diphtheria.

At a recent meeting of the Society of Physicians of Lower Austria, certain practitioners reported on the results of the antitoxin treatment of diphtheria as seen in their private practices. All the speakers agreed that the treatment was highly satisfactory. Last week the first preparations of the serum prepared in the Austrian State establishments, under the care of Professor Paltant of Vienna, were administered at the Vienna Hospital for Sick Children; and it is hoped that by the end of next month it will be possible to supply the practitioners of the empire with this remedy. A second discussion will take place at the Vienna Society of Physicians early this month.

Hypnotism in Hungary.

The Hungarian Government is now intending to prohibit by law the practice of hypnotism by all except physicians. In Austria hypnotic proceedings are strictly relegated to physicians who have graduated since 1851.

Cholera in Austria.

Cholera is now gradually decreasing in Galicia, and the number of cases in the past week has been reduced to 177, with 94 deaths; but it is feared that the epidemic may show more activity in the spring. The epidemic at the present moment not being very fierce would, it seems, afford a good opportunity for studying its course and causes; but the Austrian Government, no less than the leading medical lights here, do not apparently take any great interest in what is a chronic question with them. The study of the disease is practically neglected, and the therapeutic measures used are all on the old lines.

The General Hospital Question in Vienna.

The desolate condition of the buildings of the medical department of the celebrated Vienna University is well known to all, medical and lay, who visit Vienna. The Government have promised for years to erect new clinical wards, but it would seem that the consideration of this question is now postponed *ad calendas græcas* by bringing forward a new project. This consists of the erection of a big general hospital outside the town to take the place of the present general hospital which is located centrally. The whole faculty is in opposition to this new scheme, and naturally.

The Resignation of Dr. Wekerle.

All who have visited Hungary during the last two years, and especially the members of the last International Congress of Hygiene and Demography held at Budapest, will learn with the deepest regret that Dr. Wekerle, their amiable host, has resigned his high official position as "minister-president." If it is his eager activity that Hungary has to thank for much of her progress in the fields of public sanitation.

THE INDIAN MEDICAL CONGRESS.

As we announced last week the work of the Indian Medical Congress was begun at Calcutta on Christmas Eve, when Surgeon-Colonel R. Harvey delivered the opening address. From the list of papers we then published it will be seen that the subjects discussed covered a wide field of medical science, and we propose to present these papers to our readers as far as space will permit. The proceedings closed on Dec. 29th, after a most successful session.

THE SECTIONS.

MEDICINE.

Nasha Fever.

Mr. LAWRENCE FERNANDEZ, L.R.C.P. & S. Edin., &c., read a paper on Nasha Fever, the Nakra Fever of the North-West Provinces, otherwise called Nakra Jawhar, which is a type of fever peculiar to India, and is, perhaps, most prevalent in Bengal. Mr. Fernandez explained that the disease is characterised by a sharp attack of fever of a remittent type. It is sometimes intermittent; the temperature is always over 100° F., even when intermittent. Preceding the fever a peculiar characteristic congestion of the bloodvessels of the mucous membrane of the septum narium, as also of the Schneiderian membrane, takes place. This congestion, even after the accession of the fever, is really what attracts attention. The congestion sometimes takes place on one side of the septum, and sometimes both sides are affected. There is very often no pain; the surface of the septum is raised and presents a red appearance. Some practitioners consider this swelling and the accompanying fever to be local manifestations of a slight congestion of the brain—a belief in which the reader of the paper is inclined to concur. Others consider the swelling to be a catarrhal condition of the mucous membrane of the nose. The usual symptoms of fever are present, marked constipation and malaise are very prominent, and the appearance of the patient may be well defined by his being compared to having a "hazy" or "smoky" appearance. The nervous symptoms are peculiar. There is great frontal headache, also severe pain at the back of the neck, shoulders, and small of the back. Sometimes the pain at the back of the neck is very severe, and the accompanying febrile symptoms remind one of tuberculous meningitis. The face appears flushed, with a feeling of heat and fullness in the head and the pupils are contracted.

These symptoms continue from three to five days, when the swelling decreases and the fever subsides without any treatment whatever except the regulation of the bowels by a purgative. The swelling never suppurates. On the sudden subsidence of the swelling, which does occasionally occur, grave symptoms sometimes follow; the fever becomes higher, then delirium, coma, and death, but such a fatal result is rare. Occasionally, with the fever and nasal inflammation, an ill-defined rash appears on the body, rose coloured and in small patches, with which there are generally bronchial symptoms. Neither antipyretics nor antiperiodics have any effect on the disease. One attack predisposes to another, but the prognosis of the individual attacks is favourable. Both sexes are liable; but females are rarely attacked and never before puberty, and males not before the age of thirteen or fourteen. It does not occur after the age of fifty. The disease is prevalent between April and August, and is seldom seen in winter. The attacks occur at intervals of a month, a fortnight, or a week. All classes are liable, but the disease is most often seen in native fishermen, *dhobies*, gardeners, and *dhangurs*. Mahomedans in Bengal are not as prone to it as Bengalees. All occupations necessitating exposure to inclement weather tend to induce the disease. It is believed that the eating of stale cooked rice with cold water—a practice very common among the poor of Bengal—as also the drinking of the water from young cocoanuts, and the eating of the very young palm induce the disease, and anything which lowers the vitality predisposes to an attack. Opinions are divided as to whether Nasha fever is due to malaria, but quinine has no effect. It is prevalent in malarious places, and the fever which accompanies or follows it is preceded by ague. Opium is said to give great relief, whereas arsenic has no effect. There is congestion of the mucous membrane of the nose and frontal sinuses. The mucous membrane is slightly raised, but there is no inflammation. On pressure there is a doughy feeling, but suppuration never occurs. The mucous membrane becomes hypertrophied after repeated attacks. The blood which escapes on puncture of the nasal tumour is of a darkish colour and poor in plasma. Examination of the blood under the microscope shows an increase in the number of colourless corpuscles, the red corpuscles being crenated. Arsenic and quinine have no effect on the disease, but opium relieves the pain in the neck, back, &c. Tartar emetic used as a diaphoretic gives good results. A brisk saline purgative is all that is needed in the simpler cases. The usual method of treatment and that which gives most relief is depletion, which is done either—(1) by two bundles of *dhool* grass introduced into the nostrils, friction and pressure (native method); (2) by pricking with a needle; or (3) by a few punctures with a bleeding lancet. A small quantity of blood escapes and the sufferer is restored in a few hours to perfect health. This plan of treatment, however, is only palliative. The great objection to it is that frequent repetition conduces to hypertrophy of the mucous membrane. The local application of astringents, such as a solution of tannic acid, or a 10 per cent. solution of cocaine, sometimes gives relief. The application of akanda juice (*Calotropis gigantea*) to the mucous membrane also gives relief. The plan which Mr. Fernandez has adopted is a brisk purgative and the injection of cold water or iced water up the nostrils twice or thrice a day, with diaphoretics internally.

A paper on the same subject was read by Mr. NARESH CHANDRA MITRA, M.A., M.B. He said: "Internal remedies are useless. Only local treatment is effectual. This consists in free puncture of the Schneiderian mucosa over the swelling, which is followed by free hæmorrhage and immediate relief. The local application of lunar caustic, or of the milky juice of akanda, is also recommended."

Mycetoma.

Assistant-Surgeon J. E. BOCARRO, L.M. & S. Bombay, Hyderabad, Sindh, discussed the subject of Mycetoma. He said: "The scientific history of mycetoma, or madura disease, dates from the year 1874, when Dr. Vandyke Carter published his invaluable monograph demonstrating its parasitic nature. Dr. Carter's investigations led to the conclusions that both forms, the black and the pale, or the melanoid and ochroid varieties, resulted from the infection of one and the same parasite, the chionophye Carteri. The pale form was supposed to be merely a defaced state of the black. Drs. Lewis and Cunningham admitted the fungoid nature of the black particles, but were disposed

to consider them as accidental growths, and not in any way connected with the causation of the disease. The fungoid nature of the roe-like particles in the white variety they denied *in toto*, regarding them merely as metamorphosed fat. Recent investigations in Europe confirm the parasitic nature of the disease. Bassini in 1888 pointed out the mycelial nature of the tumour in a case of the black variety in Italy. Dr. Kanthack in 1892 likewise demonstrated the fungus origin of the disease, and attempted to identify it (the white variety) with actinomycosis. In 1893 Dr. Boyce and Dr. Surveyor demonstrated both forms of this disease as being essentially fungoid growths, and, more than that, they have been able to indicate differences under the microscope existing between the fungi of the two varieties of the disease. They say: 'We, on the other hand, will bring forward reasons for believing there are at least two distinct fungi—one a very highly organised species, the other a very delicate and lowly organised type, presenting very many of the characters of actinomycetes'; and they further add that, while some of the leading features of the roe-like particles favour a relationship with actinomycetes, from others they cannot, in their present state of knowledge, draw any conclusions. In the course of the past year Dr. Boyce forwarded to the Civil Hospital, Hyderabad, Sindh, a number of glycerine-agar tubes for inoculation, and these Dr. Keith (late civil surgeon, Hyderabad) and myself inoculated with particles from fresh specimens of both black and white varieties. Of these inoculations Drs. Boyce and Surveyor write that they have not yet been able to cultivate the black fungus; but that in the case of the white variety they have met with success. From these cultivations it is seen that the streptothrix from the white variety of mycetoma resembles very closely the streptothrix of actinomycetes. Subcutaneous inoculation of rabbits, guinea-pigs, monkeys, and rats with the artificial culture just referred to gives rise to a local reaction, and following it the production of a tumour of slow growth, which on section is found to bear the characters of the original inoculated matter. I may add that in my hands direct inoculation of rabbits and dogs with fresh particles from either variety has hitherto proved a failure. With regard to the fungus origin of the disease, the fact that the disease begins *ab externo* has an important clinical bearing. Clinical observations made by me in the Civil Hospital, Hyderabad, help to establish this conclusion. All cases of early growths have been cases of superficial growths. Dissection of the growth during operation, or sections of the diseased part after excision or amputation, afford evidence of the disease beginning generally in the loose cellular tissue, often in the subcutaneous cellular tissue, thence subsequently extending along muscular and tendinous sheaths to the other soft structures, and finally invading the hard structures. The observations apply, in all respects, to both forms of the disease, the black and the pale. The clinical points are as follows: 1. The cause assigned—viz., wounds, sores, the prick of thorns, &c. The *babul* (*Acacia arabica*) thorn is frequently mentioned as the primary source of irritation, and I have myself many times detected the points of these thorns embedded in the tumour. 2. The occupation of the patient, the disease being common among tillers of the soil or in those who have at some time or other of their lives exposed themselves to influences such as commonly surround people of the agricultural class—e.g., boatmen, shepherds, pedlars, potters, &c. 3. The common seat of the disease, the feet and hands being generally affected, the former in the majority of cases. In over 90 per cent. of the cases observed in the Hyderabad Civil Hospital these were the usual situations. 4. Lastly, and above all, the fact that the disease could be completely eradicated by excision of the superficial growth. As regards the consideration whether the varieties are simply transitional stages of one and the same fungus, as Dr. Carter holds, or whether the two forms are perfectly independent of each other in their morphological nature, as Drs. Boyce and Surveyor have pointed out, I adduce the following clinical points in evidence of the latter view. (a) The general historical data for either variety are the same, with the important difference that in all cases patients have distinctly stated, with reference to both forms, that from the very earliest indication of the existence of the growth, when one or more mammillated excrescences appeared upon the surface and burst, the sinuses gave exit throughout the course of the disease either to pale or black particles, but never to both kinds at the same time, or to one kind first and at a later date to another. (b) Anent the

idea of defacement of the fungus, while one would naturally expect a period of stasis in the growth of the tumour, there was, on the contrary, following the periodical extension of particles, observed a more or less gradual increase in its size, and in no instance was there noted at any time limitation or retrogression of the growth. (c) Sections and cross-sections have not, in my experience, shown any admixture of the two kinds of fungoid particles in one and the same specimen; on the other hand, there was a curious completeness manifest in the anatomical characters of each individual variety. (d) In the dissection of infiltrated parts, on following up the advancing course of the disease along tendons, fascia, and areolar tissue to its termination, where it must be admitted the disease is to be found in its earliest stage of development, there are invariably discovered pale particles in the pale kind, and black particles in the black kind. So far as the naked-eye appearance goes, there are no transitional stages of growth from one to the other. (e) Careful excision of these terminal sites of the disease effectually cuts off all chances of recurrence; if not, the disease tends to relapse, in which case the pale variety is followed by the pale and the black by the black form of growth."¹

OBSTETRICS, DISEASES OF WOMEN AND CHILDREN.

Biliary Cirrhosis of Children.

Mr. Jogendro Nath Ghosh, L.M.S., dealing with this disease, said: "Its onset is insidious, it usually prevails among infants under the age of one year, and it seldom attacks children after they have passed the third year. The attack generally commences about the seventh or eighth month, chiefly at the period of dentition or at the mother's next conception. The children of some parents are particularly liable to the disease. In one family I have observed fourteen children of the same parents die one after the other. Cases of attack about the third or fourth month, or even a few days immediately after birth, have also been noted. Children in Calcutta, as well as in the districts of Lower Bengal, whether malarious or non-malarious, are equally subject to it. It spares neither the rich nor the poor, though the well-fed children of the wealthy and the middle classes are more liable to it than the ill-fed children of the poorer classes. Mahomedan and Eurasian children suffer less than Hindus. Hardly any cases are seen among Europeans. Children who are never or only for a short time put to the mother's breast, and are fed on cow's, goat's, or ass's milk, or with different kinds of artificial food, enjoy no immunity from this disease. In families where the disease has prevailed I have noticed a few children escape apparently from being nourished by healthy wet-nurses. When the disease was first noticed in Calcutta more cases were found among male than among female children, but of late the proportion seems to be less. The female children mostly attacked are usually the first-born of the parents, and are the objects of great care in a family. It has been observed that a female child escapes the malady after the successive deaths of several males who preceded her, though again the next male child succumbs to it. Children of very healthy parents are not exempt, and the disease appears to be quite unconnected with long-standing purulent discharges, scrofula, syphilis, malarious fever, or any chronic constitutional disease. It has also been noticed that in some cases the later children of some parents escape the disease after the earlier ones have all died from it. The enlargement of the liver is gradual and is unattended with pain. The subsequent contraction is, however, rapid. The termination is generally fatal, death being mostly due to cholæmia. The disease runs its course in from three to twelve months, though one case has been known to end fatally within a fortnight of the attack; but in two other cases the patients had lingered for three years. In my experience, out of about 400 cases only six have recovered. Persistent jaundice, I believe, prognosticates a fatal termination. The disease may be defined as a painless enlargement of the liver, hard and resistant to the touch, beginning with slight fever, occurring in children only, and terminating almost invariably in death. Usually the first symptoms are that the liver has attained a considerable size before anything is suspected. The symptoms which attract the mother's notice are nausea, occa-

sional vomiting, sallow complexion, warmth of hands and feet, and a certain amount of constipation and straining at stool. The child refuses food, gets irritable, wishes to lie on damp ground, and has a little fever towards night or early in the morning. Thirst and an icteric tinge are also noticed. When the child is brought under the physician's observation the liver is usually enlarged, at times so considerably that it extends as far as the umbilicus or even beyond it to the iliac crest. The anterior margin of the liver is well defined, prominent at first, and feels smooth and rounded; gradually it becomes thinner, assuming the shape of a knife-back edge, and at the last stage it can be grasped by the fingers. The enlargement is uniform, hard, and resistant, painless at first, but gradually getting painful when jaundice supervenes. The left lobe generally enlarges first, sometimes reaching as far as the spleen, which also in most cases enlarges simultaneously. Occasionally the right lobe enlarges so much that its anterior border overlaps the left lobe, and the notch between the lobes is so displaced to the left as to be mistaken for the hilum of the spleen. The liver gradually fills the abdomen, which bulges, and the superficial veins become prominent. At first there is no marked change; after a time the features exhibit a dusky appearance; later the skin becomes hard and dry and the complexion slightly yellow; the feet and hands may become puffy. The spleen is generally hard and enlarged, and constipation is a well-marked, obstinate symptom. The stools are yellowish at first, then clayey and muddy, and lastly whitish and devoid of bile. The urine, from being clear, gradually becomes bile-tinged, and lastly deep yellow, saffron-coloured, the stain of which does not disappear on washing. There is very little or no perspiration. Fever is slight at the beginning, but it increases with the progress of the disease, and the maximum is reached when the jaundice is pronounced. The fever is not preceded by any rigor as in ague. In some cases fluid accumulates in the peritoneal cavity, with œdema of the hands and feet. The onset of the intense and persistent jaundice which occurs in the later stage of the disease is a symptom of the gravest import. After the appearance of jaundice the size of the liver diminishes. In a few cases I observed the contraction to be so very rapid that in forty-eight hours it receded from the umbilicus to within the margin of the costal arch. The contraction has often been mistaken for a favourable symptom. The main causes of this serious malady are, I believe, unwholesome food and faulty digestion. The milk either of the mother or of the cow is the principal article of food for our infants. Mahomedans and Eurasians feed their children occasionally with animal broth. The Hindu mother always nourishes her children from her own breast, and it is among the Hindus that the disease is most prevalent. As regards the mother's milk, the practice is not uncommon for a mother in a state of pregnancy to suckle her child. Her system must then be undergoing a change, rendering her milk quite unfit for the child she is nursing. Cow's milk is so much adulterated in large centres of population that it is quite unsuitable for infant food. Besides adulteration of milk, the cows are kept in unhealthy sheds and fed with refuse &c. Great carelessness also prevails in keeping the milk. The vessels are not properly cleaned, and stale milk is often sold as fresh. Irregularity in feeding and over-feeding the infant are common. Whenever it cries milk is poured down its throat in order to pacify it, irrespective of quantity or quality or the time or the interval after which it is fed. The duration of the disease is from three to nine months, death usually occurring from the fifteenth to the eighteenth month of life. The prognosis is extremely unfavourable. In my experience out of about 400 cases only six recovered, but in three of them the diagnosis is open to doubt. Treatment is most unsatisfactory because the parents will not carry out the directions prescribed. I believe the best hope of success lies chiefly in change of diet. I always forbid the mother to suckle the infant, and substitute a healthy wet-nurse or a specified quantity of cow's milk suitably diluted according to the age of the infant. Many medicines have been tried—e.g., mercury, iodide of potassium, hydrochlorate of ammonia, phosphate of soda, &c., but I cannot attribute any benefit to them. Laxatives and cholagogue purgatives are required for the obstinate constipation of the early stage. Recently I have been using the freshly prepared juice of the leaves of *Nyctanthes arbor tristis* or the *sini*, in teaspoonful doses taken in the early morning, and this has usually acted well except in the late stage of marked jaundice. Change of climate is undoubtedly beneficial in the early stage, but later it has no effect."

Medical News.

UNIVERSITY OF LONDON.—The following gentlemen have passed the B.S. examination for Honours in Surgery:—

FIRST CLASS.

Fisher, John Herbert (Scholarship and Gold Medal), St. Thomas's Hospital.
 Davies, Hugh (Gold Medal), Guy's Hospital.
 * Wallace, Cuthbert Sidney, St. Thomas's Hospital.
 Richardson, Sidney W. F., B.Sc., St. Thomas's Hospital.

SECOND CLASS.

Smith, William Robert, King's College.
 Cowen, George Hebb, London Hospital.
 * Obtained the number of marks qualifying for a gold medal.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin*: Dr. Loewy has been recognised as *privat-docent* in Physiology, Dr. M. Mendelsobn as *privat-docent* in Medicine, and Dr. Wernicke as *privat-docent* in Hygiene. Professor Kohlrausch of Strasburg has accepted the offer of the charge of the Physico-Technical Institute in succession to Professor Helmholtz.—*Paris*: Dr. Arsonval has been appointed to the chair of Medicine in the Collège de France in succession to M. Brown-Séquard.—*Montpellier*: Professor Mairet has been appointed Dean of the Medical Faculty for three years.—*Lemberg*: Dr. Josef Nusbaum has been appointed Professor of Descriptive Anatomy and Histology, and Dr. Johann Prus Professor of Pathological Anatomy and General and Experimental Pathology.—*St. Petersburg* (Military Medico-Chirurgical Academy): Dr. Skorichenko has been recognised as *privat-docent* in General and Experimental Pathology.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Josef Schröter of Breslau, where he ranked as professor; he was a great authority on fungi. His death, which was somewhat sudden, was due to an affection of malarial origin, the foundation of which was laid in his last summer's journey for botanical research to the southern part of Asia Minor.—Professor F. A. Flückiger, a well-known author of pharmaceutical works. Until a year or two ago he was professor at Strasburg, but was then obliged to give up work on account of ill health. He had since been residing in Berne, where he died.—Dr. Studiali, Professor of Physiology in the University of Pisa.—Dr. Yermolayeff, formerly Professor of Anatomy in Kazan.—Dr. L. de Crecchio, Professor of Forensic Medicine in the University of Naples.

BEQUESTS AND DONATIONS TO HOSPITALS.—The late Mr. Samuel M. Gibbs of The Mount, St. Leonards-on-Sea, has bequeathed £250 each to the Hospital for Women, Soho-square, London, and the Samaritan Free Hospital for Women and Children, Marylebone-road.—Mr. George Hibberd, late of Leyton, has bequeathed £1000 each to the London Hospital and the City of London Hospital for Diseases of the Chest, Victoria-park, and £250 each to the Convalescent Home at Bexhill, the Convalescent Home, Walton-on-Thames, the Children's Hospital, Walthamstow, the Walthamstow Dispensary, and Mrs. Gladstone's Convalescent Home at Woodford.—The late Mr. John P. Kidston of Northaw, Herts, has bequeathed £250 each to the Potter's Bar Hospital and the Herts Convalescent Hospital.—Vice-Admiral C. F. F. Boughie, late of Richmond, Surrey, has bequeathed £100 each to the Hospital for Diseases of the Chest, Brompton, and the Free Cancer Hospital.—The late Mr. James E. B. Stevenson of Clapham-park has bequeathed £100 to the British Home for Incurables, Clapham-rise.—The Corporation of London has voted the following grants—namely, 50 guineas to the Brixton, Streatham-hill, Herne-hill, Tulse-hill, and Angell Town Dispensary (commonly called the Brixton Dispensary); 100 guineas to the Middlesex Hospital; 75 guineas to the West Ham Hospital; 25 guineas to the Livingstone Cottage Hospital for Dartford and District; 100 guineas to the City of London Hospital for Diseases of the Chest; 50 guineas to the Great Northern Central Hospital, Holloway-road, 20 guineas to the Brabazon Home of Comfort for Incurables at Reigate; and 20 guineas to the Women's Convalescent Home Association at Great Woking.—The late Mr. Thomas Dunn of Prince's-gardens, South Kensington, has bequeathed £105 each to the Royal Sea Bathing Infirmary at Margate, St. Thomas's Hospital, London, St. George's Hospital, London, King's College Hospital, London, York County Hospital, the General Infirmary,

Gloucester, and the Cheltenham Hospital.—Mr. George Simpson, late of Wray Park, Reigate, has bequeathed £250 each (free of legacy duty) to the Children's Convalescent Home at St. Leonard's-on-Sea, the Hospital for Women, Soho-square, London, and the Samaritan Free Hospital for Women and Children, Marylebone-road.—An anonymous friend has sent a donation of £100 to Guy's Hospital, London.—The directors of the Dundee Royal Infirmary have received a donation of 400 guineas from Mr. and Mrs. David Carmichael of Dudhope-terrace for naming two cots in the children's ward of the infirmary. Towards the New General Hospital Fund, Birmingham, £100 have been received, being the net proceeds of the recent cycle parade, and a further sum of £100 has also been received from the Muffs and Duffers charity cricket match.—Mr. Henry Whiting has given a donation of £100 to the Chelsea Hospital for Women, and £10 to the Convalescent Home in connexion with it.—The late Rev. George Heron of Moore, honorary Canon of Chester, has bequeathed £300 to the Hospital for Incurables, Putney Heath.—Messrs. Maple of Tottenham-court-road, London, have contributed £100 each to the North-West London Hospital, the Royal Free Hospital, the Temperance Hospital, and the University College Hospital, London.—£100 have been handed over to the St. John's Convalescent Home for Children, Kemp Town, Brighton, being the net proceeds of the ball recently held in aid of that institution.—The honorary treasurer of the Wirral Children's Hospital has received a donation of £150 from Miss Laird in memory of her late brother, Mr. Macgregor Laird.—Miss Mary Smith, late of Watford, Herts, has bequeathed £100 to the Cottage Hospital, Maidenhead.—A lady, under the initials of "H. M. E.," has sent a donation of £500 to the Chelsea Hospital for Women.—The late Mrs. Sophia Fletcher of Pull-court, Tewkesbury, has bequeathed £100 to the British Home for Incurables.—The Goldsmiths' Livery Company has voted £50 to the British Home for Incurables.—The Lord Lieutenant of Cambridgeshire has given another donation of £1000 to Addenbrooke's Hospital, Cambridge.—Under the will of the late Mrs. S. E. Baker of Bromsgrove, the Trustees have decided to apportion the sum of £7000 to the Bridgnorth and South Shropshire Infirmary.—Mr. John Johnson, late of Seacroft, has bequeathed £500 to the Leeds Hospital for Women and Children.

FOOTBALL CASUALTIES.—The following accidents occurred on the 25th, 26th, and 29th ult., and the 1st inst. At Barnsley, in a match between the High School Boys' Club and Barnsley Victoria team, a player fractured his ankle, and was conveyed to the Beckett Hospital.—A Leigh half-back, while playing against the St. Helens team, at St. Helens, sustained a fracture of his breast bone, and was removed to the St. Helen's headquarters.—At West Derby, a youth, while playing a match, fractured his leg and was injured "internally."—During a match at Reading between the London Caledonian Strollers and the Reading Reserves, a player fractured his clavicle.—At Southampton, in a match between the Bournemouth Wanderers and the St. Mary's Reserves, a player fractured his clavicle and was taken to the Royal South Hants Infirmary.—In a match at Yeovil a player fractured his clavicle.—At Crewkerne in a match a player broke his arm.—A youth while playing at the same place also fractured his arm, and was admitted to the hospital in that town.—At Ferrybridge a youth aged twelve years died on Saturday last from an injury received while playing a game on the previous Wednesday.—At Leith, in a match between the Leith Athletic and Sheffield United teams, the centre half-back of the United League team dislocated his knee, and "seriously injured his ankle."

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

ASHBY, T. H., M.B. Toronto, M.C.P.S. Ont., L.R.C.P. Lond., has been appointed Medical Officer to the Workhouse of the Shardlow Union.

BRACEWELL, W. H., M.B., Ch.B. Melb., has been appointed a Government Medical Officer and Vaccinator for the district of Condobolin, New South Wales.

CHAPMAN, JOHN T., L.R.C.P., L.M., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Public Vaccinator at Stratford, Victoria, Australia, vice Matthews, resigned.

FETHERSTONHAUGH, CHAS., M.B., Ch.M. Dubl., L.R.C.S. Irel., has been appointed Health Officer for the Glenlyon Shire, Victoria, Australia.

GRANT, A., M.B., Ch.M. Aberd., has been appointed Health Officer for Oakleigh, Victoria, Australia.

HAWTHORN, W. T., M.R.C.S., has been reappointed Medical Officer for the Northern (No. 1) Sanitary District, and also Medical Officer of Health, of the Wellington Union.

HEWER, H. J., M.B., Ch.B. Melb., M.R.C.S. Eng., has been appointed Visiting Surgeon to the Blackall Prison, Queensland.

HOSKING, WM. H., M.R.C.S. Eng., L.K.Q.C.P., L.M. Irel., has been appointed a Public Vaccinator for the Masterton District, New Zealand.

HOUSE, S. HERBERT, M.B., Ch.B. Viet., has been appointed Resident Medical Officer to the Grimsby and District Hospital.

HOYLE, J. C., L.R.C.P. Lond., M.R.C.S., D.P.H., has been appointed *pro tem*, Medical Officer of Health for Holborn.

HUGHES, W. K., L.R.C.P. Lond., M.R.C.S., has been appointed Specialist for Deformities by the Sisters of Charity, in connexion with St. Vincent's Hospital, Melbourne, Victoria, Australia.

KELLYNACK, T. N., M.D. Viet., Ch.B. (Owens College), has been reappointed Pathological Registrar to the Manchester Royal Infirmary.

LAWES, C. H. E., M.B., Ch.M. Syd., has been appointed Resident Medical Officer to the Brisbane General Hospital, Queensland.

LEWIS, ERNEST WOOL, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Assistant Anesthetist to the West London Hospital.

LOVEGROVE, CHAS., M.D., Ch.M. Toronto, L.R.C.P. Edin., L.M., L.F.P.S. Glasg., has been appointed Surgeon-Captain to the Western Australia Volunteer Force, Western Australia.

MAHONEY, R. W., M.B., Ch.B. Viet., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Medical Officer to the Munsell Fever Hospital.

MCALLISTER, J. F., M.D. Melb., Ch.B., has been appointed Honorary Assistant Surgeon to the Prince Alfred Hospital, New South Wales.

MILLIGAN, WM., M.D., M.Ch. Irel., has been appointed Medical Officer for the Cumberland Sanitary District of the Huddersfield Union.

MULLER, H., M.D. Marb., has been appointed Honorary Medical Officer to the Carrington Convalescent Hospital, New South Wales.

PATTON, A. S., M.D. Dubl., Ch.B., has been appointed Visiting Surgeon to the Normanton Prison, Queensland.

PLANCE, CHARLES, jun., M.A. Cantab., L.R.C.P. Lond., M.R.C.S. Eng., late House Surgeon to St. Thomas's Hospital, has been appointed Junior Assistant Medical Officer to the East Sussex County Asylum, Haywards Heath, vice F. D. Bennett, L.R.C.P., M.R.C.S., resigned.

PROPERT, WALTER ARCHIBALD, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Physician to the West London Hospital.

RENNIE, GEO. E., M.D. Lond., M.R.C.S., has been appointed Honorary Assistant Physician to the Prince Alfred Hospital, New South Wales.

RIORDAN, T. F., M.D., Ch.M. Irel., has been appointed Honorary Physician by the Sisters of Charity, in connexion with St. Vincent's Hospital, Melbourne, Victoria, Australia.

ROBERTS, CHAS. G., M.B., B.C. Camb., has been reappointed Medical Officer of Health to the Halstead Local Board.

SAMSON, H. A., M.B., Ch.B. Melb., has been appointed Acting Medical Superintendent to the Ballarat Lunatic Asylum, Victoria, Australia.

STACPOLE, A. R., L.R.C.P., L.R.C.S., L.M. Edin., has been appointed Surgeon to the Victorian Rangers, with the relative rank as Captain, Victoria, Australia.

TIPPETT, S. G., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Senior House Physician to the Westminster Hospital.

THACKWELL, J. B., M.B., Ch.M. Edin., has been appointed Medical Officer to the Hospital at Ravenswood, Queensland.

YONGE, EUGENE S., M.B., C.M. Edin., has been appointed Assistant Medical Officer to the Manchester Hospital for Consumption and Diseases of the Chest, vice Dr. Wood, resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BOLTON UNION.—Medical Officer for the Workhouse at Fishpool, for twelve months. Salary £200 per annum and a furnished house. Applications to the Clerk to the Guardians, 23, Mawdsley-street, Bolton.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's-inn-road,—Assistant Registrar for twelve months.

COUNTY ASYLUMS, Prestwich, Manchester.—Phthisicologist. Salary £200 per annum, with furnished apartments, board, attendance, and washing.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY, Chesterfield.—Junior House Surgeon and Dispenser. Salary £50 per year, with board, apartments, and laundress.

FISHERTON ASYLUM.—Assistant Medical Officer, single. Salary £100 per annum, with board, lodging, and washing. Applications to Dr. Finch, Salisbury.

LONDON HOSPITAL MEDICAL COLLEGE, Turner-street, Mile-end, E.—Lectureship on Organic Chemistry. Salary not less than £175 a year.

VICTORIA HOSPITAL FOR SICK CHILDREN, Queen's-road, Chelsea, S.W.—House Surgeon to the In-patients. Honorarium £50 per annum, with board and lodging in the Hospital. Also House Physician to the In-patients. Honorarium £50 per annum, with board and lodging in the Hospital.

Births, Marriages, and Deaths.

BIRTHS.

CRANE, On Dec. 29th, at Sandgate-road, Folkestone, the wife of Andrew J. Crane, L.D.S., of a daughter.

DAY.—On Dec. 23rd, at Baldock, Herts, the wife of F. W. Langston Day, M.R.C.S., &c., of a son.

D'ESTERRE.—On Dec. 27th, at Albion Cottage, Fortis Green-road, East Finchley, the wife of J. Norcott d'Esterre, jun., L.R.C.P. Lond., M.R.C.S. Eng., of a daughter.

GRAY.—On Dec. 30th, at Prescott-road, St. Helens, Lancashire, the wife of Andrew Gray, M.D., of a daughter.

O'CALLAGHAN.—On Dec. 28th, at Harley-street, W., the wife of Robert O'Callaghan, F.R.C.S.I., of a son.

MARRIAGES.

CLAYTON—JARVIS.—On Dec. 29th, at St. Luke's, Redcliffe-square, Charles Clayton, M.R.C.S., L.R.C.P., of Broadhurst-gardens, N.W., to Ellen, daughter of the late W. Jarvis, of South Kensington.

HIRSCH—MOREY.—On Oct. 29th, 1894, at the Holy Trinity Church, Suva, Fiji, by the Rev. Francis Jones, M.A., Charles Theodore William Hirsch, M.R.C.S. Eng., L.R.C.P. Lond., F.C.S. Lond., &c., District Medical Officer, Rewa, Colonial Medical Service, Fiji, to Emmeline, fifth daughter of the late James Morey, Esq., of Fiji.

HUTTON—SMITH.—On Dec. 29th, at the Cathedral, Manchester, Henry Richmond Hutton, M.A., M.B. Cantab., of Manchester, to Evelyn Mary, elder daughter of the late G. Fereday Smith, of Grovehurst, Tunbridge Wells.

SMITH—EDMOND.—On Dec. 28th, at Blackford-road, Edinburgh, J. Lorrain Smith, M.D., son of the late Rev. Walter Smith, Half-Morton, to Ella, daughter of E. Edmond, late of the Indian Civil Service.

DEATHS.

DICKSON.—On Dec. 29th, at Royal-circus, Edinburgh, Walter George-Dickson, M.D., aged 73.

HEWITT.—On Dec. 26th, at Catford, Henry Bealey Hewitt, M.B. M.Ch. Cantab., (Clare College).

REITH.—On Dec. 30th, on board ss. *Norham Castle*, Archibald Reith M.D., Aberdeen.

STORY.—On Nov. 27th, at Telepara, near Nagrakata, Bengal, Arthur N. J. Story, M.B., aged 30.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), Gt. Northern Central (2.30 P.M.), King's College (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY.—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—Mr. John D. Malcolm: Illustrations of some Modes of Death from Ovariotomy.

WEDNESDAY.—LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—4.30 P.M. Annual General Meeting. Election of Officers and Council, &c. Cases, Specimens, &c., by Mr. A. E. Durham, Dr. William Hill, Dr. Alex. Hodgkinson (Manchester), Dr. Middleton Hunt (Liverpool), Dr. Percy Kidd, Dr. Edward Law, the President, Dr. Seanes Spicer, and Mr. W. R. H. Stewart. The Annual Dinner at the Café Royal, Regent-street, at 8 P.M.

HUNTERIAN SOCIETY.—8.30 P.M. The President (Mr. Charters J. Symonds): The Surgical Treatment of Typhilitis.—Dr. Fred. J. Smith: Notes of a case of Typhoid Fever treated by the Continuous Bath.

NORTH-WEST LONDON CLINICAL SOCIETY (North-West London Hospital, Kentish Town-road).—8.30 P.M. Exhibition of Cases.

THURSDAY.—BRITISH GYNECOLOGICAL SOCIETY.—Specimens. Reports on Specimens. Election of Officers for 1895. President's Valedictory Address.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.).—4.30 P.M. Dr. Eddowes: Explicative Dermatitis.—Dr. David Walsh: A Note on Antitoxin Rash.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY (Great Northern Central Hospital).—9 P.M. Dr. A. Morison: The Blood-pressure in Angina Pectoris.—Dr. Archibald K. Christie: Remarks on the Selection of Cardiac Tonics.

FRIDAY.—CLINICAL SOCIETY OF LONDON.—Mr. Mayo-Robson: Three cases of Abdominal Section for Unusual Conditions.—(a) Tuberculous Disease of the Liver, (b) Complete Volvulus and Strangulation of Great Omentum, and (c) Traumatic Hemorrhage without External Wound.—Dr. J. W. Browne: A case of Loculated Empyema.—Mr. F. Eve: A case of Acute Intestinal Obstruction from Gall-stone; Laparotomy: removal of stone; suture; recovery.—Dr. S. West: Two cases of Detachment of the Retina in the course of Granular Kidney.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

TUESDAY.—CENTRAL LONDON THROAT AND EAR HOSPITAL.—Dr. Dundas Grant: The Methodical Diagnosis of Diseases causing Deafness without Pain or Discharge.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

COVER TO THE LANCET.

THE Manager begs to announce that at the request of many advertisers, and to keep pace with the ever-increasing demand for "position" pages, it has been decided to issue a cover to THE LANCET, commencing with the present number. The cover is printed on the same kind of paper as the journal itself, and thus ensures uniformity of appearance with past issues. With this exception of the cover the journal remains exactly as it was before. The Proprietors cannot consent to the insertion of advertisements in the centre of the paper—a position which has frequently been applied for, but which is annoying to the general reader.

THE INDEX TO THE LANCET.

THE Index for the last half-year was published in our last issue, which completed the second volume of the year 1894. Those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Manager.

THE INFECTIOUS DISEASES (NOTIFICATION) ACT.

To the Editors of THE LANCET.

SIRS,—I was recently asked by a *confrère* to see two cases of small-pox with him, in order to confirm his diagnosis, which proved to be a correct one, and in due course I forwarded two certificates, as required by the Infectious Diseases (Notification) Act. Our medical officer of health writes to me that "the Act does not provide for the sending of duplicate certificates when a second medical practitioner is called in to see a case in consultation with the medical man in attendance, and I do not think that any fee is payable to you in regard to the two cases in question." Would you kindly in your next issue inform me whether, in your opinion, this is a correct view of the case, and whether a letter addressed to the Secretary of the Local Government Board would be likely to elicit an opinion as to what the law really means on the point in question—if it has not already been decided?

I am, Sirs, yours faithfully,

Birmingham, Dec. 18th, 1894. J. M. WALKER.

* * * The Act requires that every medical practitioner called in to see a case of one of the specified infectious diseases shall notify the same. Nothing is said in the Act either as to a first or second medical practitioner; neither is anything said as to first or subsequent cases of sickness. Consequently, each case has to be notified, and each case has to be paid for. If further difficulty arises, a letter should be addressed to the Secretary of the Local Government Board, specifying the actual fact and putting the question definitely, with request for an answer.—ED. L.

THE DISPOSAL OF DEAD CHILDREN.

SOME very disquieting evidence as to the disposal of deceased infants was elicited at an inquest held by Mr. G. P. Wyatt at the Newington Coroner's Court on Dec. 28th. The child of a single woman, who had been attended in her confinement by a midwife, died twelve days after birth, and on the following day the body was wrapped in brown paper, and left by the midwife at an undertaker's shop in the neighbourhood. The birth was not registered. The explanation of the omission, according to the account of the proceedings published by the *Evening Standard*, was that the midwife undertook to perform this duty, but found herself too busy to attend to it, and the mother was unable to leave the house. The coroner was communicated with and the mother admitted that she had no money to defray the expenses of a funeral, but denied that she had connived at an attempt to have the body buried as still-born; in fact, her expectation was that the midwife who removed it would "throw it over the railings and give it a cheap funeral." The undertaker's wife, to whom the parcel was delivered, was under the impression that the child had been still-born, but she added, curiously enough, that the midwife "promised to bring the certificate on the following Monday." The jury returned a verdict of death from malnutrition and considered the conduct of the midwife very reprehensible.

C. E. P.—A circular to *bond fide* patients on change of tenure in a practice, and where personal introduction is impracticable, is permissible; but the advertisement of low charges is very objectionable. The period of three years seems rather long, and might easily cover the circulation of the document among the patients of other practitioners, which should be avoided.

F. E. C.—No powers exist in this country of "quarantining" healthy persons in the way suggested as desirable at Guernsey, though Leicester has assumed such a power. Compulsory removal to hospital with us is made under Section 124 of the Public Health Act, 1875. Guernsey is, we believe, under the jurisdiction of the Home Office as regards these matters.

A District Medical Officer would be glad to know if there exists a handbook for the guidance of parish doctors in their duties and obligations, and written rather directly from their point of view.

"MUCUS IN THE EVACUATIONS."

To the Editors of THE LANCET.

SIRS,—In reference to a letter under the above heading, which appeared in THE LANCET of Dec. 15th, 1894, p. 1461, I, like "A Reader," should be glad to know the causation, pathology, and proper treatment of this disease. The literature of the subject is limited. Under the heading, "Chronic Mucus Colitis," some twenty years ago or more, the late Sir Andrew Clark and Dr. Habershon wrote separately some articles on this subject, which appeared in THE LANCET of the time. Pseudo-membranous colitis is due, according to some writers, to a lesion of the spinal cord. I believe that chronic mucus colitis is somewhat similar and due to exhaustion of the nerve centres of the lumbar portion of the cord; that when the inješta reaches the colon the glands in this portion of the intestine are unduly excited, the more so if the digestion in the stomach or duodenum be faulty. All astrinents, I believe, are useless either given by the mouth or rectum. Purgatives are harmful. If constipation exists I should recommend an enema to be given once a day, preferably in the morning. Strychnine and so-called spinal tonics over-excite the cord and make matters worse. In my experience the only drug effectual in this disease is dilute hydrocyanic acid $\frac{m\text{ij}}$ after food. The diet should be of the most digestible form. Vegetables, owing to their large residue, should be taken sparingly. A glass of good port wine might be given at dinner, according to the age of the patient. Smoking and alcoholic excess should be interdicted, as also late hours and anything of an exhausting tendency.—I am, Sirs, yours truly,

Dec. 19th, 1894.

S. W. WILSON.

Messrs. Dawson & Sons, of Bream's-buildings, Chancery-lane, have sent us one of their "Ceres" Letter File Boxes, which appears to be an excellent contrivance for keeping in order and ready to hand, at a moment's notice, a maximum of papers, memoranda, &c., with a minimum of trouble. After a trial we shall be the better able to pronounce a more definite opinion upon its value.

J. S. R.—Our correspondent points out a condition of things worse than we had imagined, and we knew the condition to be bad. His communication shall receive our most serious attention.

THE DUTIES OF A VOLUNTEER BRIGADE-SURGEON.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me of a book where I may learn the duties of a volunteer brigade-surgeon when in camp? I have the Regulations for Army Medical Services and Standing Orders of Army Medical Staff, 1894, but it does not mention the duties during encampment.

Dec. 29th, 1894.

I am, Sirs, yours truly,

VOLUNTEER.

AN UNANSWERABLE EXPLANATION.

At page 48 of his book, entitled "The Vaccination Question," Mr. Hutton, a well-known antivaccinationist, writes as follows:—

"Revaccination became the cry a few years ago, and the cry has quite lately been extended to 'frequent' or (what amounts to the same thing) 'recent revaccination,' which we are now assured is the only genuine and absolutely safe defence. Of course, this doctrine drives a coach-and-four through legislation which insists only on vaccination in infancy, and it also renders a little ridiculous the horror which many advocates have professed to feel at the state of unvaccinated infants as 'centres of infection.' Dr. Seaton recommended revaccination at puberty, but objected to a third repetition of the operation. On the other hand, Dr. Collingridge, the active medical officer of health for the port of London, advocates thoroughly efficient annual revaccination."

This argument, deriding the alleged necessity for annual revaccination, has been used by Mr. Milnes as well as by Mr. Hutton, and appears to have been based on a summary of a report made by Dr. Collingridge and published in *The Times* on July 14th, 1881. Unfortunately for Mr. Hutton's fancied triumph, Dr. Collingridge writes in *The Times* of Dec. 27th, 1894, referring to the above-mentioned summary, and points out that "annual vaccination" was by a printer's error substituted for "animal vaccination," which was the very different expression really employed in Dr. Collingridge's report. We are not aware that Mr. Hutton has, as he surely should do, made a courteous and graceful apology to Dr. Collingridge for the mistake into which he was unwittingly led.

G. C.—There is nothing contrary to professional etiquette in sending to the patients whose names are upon the books of the previous owner of the practice a notice that the practice has been transferred. Such circulars should not be sent to the patients of other practitioners, and good taste will prevent them from constituting anything more than a formal announcement.

Surgeon.—The question our correspondent asks is a large one, and the facts as stated are hardly sufficiently detailed to enable us to give an explicit reply.

THE SUPPLY OF STERILISED MILK.

To the Editors of THE LANCET.

SIRS,—We have seen your interesting article with reference to the supply of sterilised milk in New York, and with regard to your concluding remark, that "the question of sterilising milk is well worthy of careful consideration, and the practical experiment made in New York should be watched and perhaps imitated," we beg to inform you that we have for many years supplied sterilised milk with great success not only in London, but to all parts of the United Kingdom, to the Continent, and even to New York, the West Indies, &c.

I remain, Sirs, yours faithfully,

RICHARD S. BOND,

Chairman the Aylesbury Dairy Company, Limited.

St. Petersburg-place, Bayswater, London, W., Dec. 20th, 1894.

"CENTRIFUGAL FORCE IN THE EXAMINATION OF SPUTUM."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Dec. 8th, 1894, reference is made to Mr. Metzger's instrument for separating tubercle bacilli by centrifugal force. Can any of your readers tell me if this has been used with typhoid bacilli; and, if so, with what success?

I am, Sirs, yours faithfully,

Jan. 1st, 1895.

SEPARATOR.

THE MEDICAL MANAGEMENT OF WORKHOUSES.

To the Editors of THE LANCET.

SIRS,—Can any of your readers oblige me by telling me what is the best source of information respecting the medical management of workhouses? What competent information is published "up to date"?

I am, Sirs, yours faithfully,

Dec. 19th, 1894.

R. N.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Bungshire Advertiser, Newbury Weekly News, Birmingham Post, Manchester Guardian, Fife Herald, Sheffield Independent, North British Daily Mail, Chester Chronicle, To-Day, Brighton Standard, Cheltenham Mercury, Devon City Standard, Glasgow Herald, Ormskirk Advertiser, Weekly Times and Echo, People's Western Morning News, Cork Examiner, City Press, Stroud News, Morning Leader, Brighton Guardian, Brisbane Telegraph, Building News, Sun, Citizen, Dorset County Chronicle, Walsall Observer, Bristol Times, Annandale Observer, Leigh Chronicle, Yarmouth Gazette, Swansea Journal, Teignmouth Gazette, Courrier de la Presse, Liverpool Courier, Australasian Medical Gazette, Guy's Hospital Gazette, Worcester Chronicle, Leamington Spa Courier, Cape Times, Portsmouth Evening Mail, Dublin Evening Telegraph, Southampton Echo, Gray's Standard, Times of India, Elgin Courier, Pioneer Mail, &c., &c.*

Communications, Letters &c. have been received from—

A Lecture

ON

SOME POINTS IN THE DIAGNOSIS OF
INSULAR SCLEROSIS.*Delivered in the London Post-graduate Course at the National
Hospital for the Paralysed and Epileptic on
Oct. 25th, 1894.*By THOMAS BUZZARD, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL.

INSULAR or disseminated sclerosis is one of the most frequent chronic diseases of the spinal cord, yet there is probably none in the diagnosis of which errors are so frequently made. I shall show you to-day five patients who, I am disposed to think, are affected with this disease, but it must be admitted that there is only one of them which is a typical example, and we had better see him first. [This patient (A.)—under the care of Dr. Bastian,—who presented characteristic tremors on voluntary movement, loss of power in various limbs, exaggerated knee-jerks, nystagmus, slow and peculiar speech, pallor of both optic discs, besides bulbar symptoms, was then shown and the nature of the disease generally described.] Were this symptom-group usually present in the perfect form just seen there would be little reason for hesitation in diagnosing the affection, but this is very far from being the case. I believe that for one typical example like this there are very many indeed the symptoms of which are so widely divergent that the idea of insular sclerosis may easily fail to present itself to anyone familiar only with the classical form of the disease. Let me show you some examples which have recently come under my care in hospital.

Patient B., a man thirty-six years of age, married, was admitted on Aug. 14th, 1894, with complete loss of voluntary power in the lower and some weakness in the upper extremities. (I am indebted to Dr. Warrington, resident medical officer, for notes of this and the following cases.) It appears that thirteen years ago his right arm felt "numb" and he frequently dropped things from it, and gradually lost power so that he ceased to be able to hold anything. His right leg also became affected; he dragged it in walking and frequently fell. There seems to have been no objective sensory change. The face was not affected. In about six weeks he recovered and was able to go about his work as usual. Very soon after this his left eye "had a fog over it," and he attended at Moorfields Hospital. "It came all right in about nine weeks." Some years after this he had a similar attack in the eye and again recovered, but the sight never seemed quite so good. Three years and a half ago he could not use the left hand, which was weak, not stiff, and the left leg became affected; he found he could not walk well, and then the right leg also became affected. For two years past he has been unable to move his legs. The right hand has also been affected at times. For eighteen months he has had difficulty in holding his urine, not being able to retain it for more than an hour, and then it runs from him. He is conscious of its passage. Nor can he retain the evacuation of the bowel long after a call. (He has had accidents.) There is no history of syphilis and nothing material in the family history. His previous general health had been good, except for a little, not severe, rheumatism. He is a fairly well-nourished man, with a somewhat dusky face and heavy expression; mentally not very bright, but his memory not manifestly impaired, and he has not lost interest in his surroundings. There are no hallucinations. His speech is rather indistinct. There is no voluntary power in the lower extremities, which are kept extended except for frequent flexor spasms. There is slight rigidity of all joints, which is easily overcome. There is no wasting and no tremor; the muscular sense is good. On the left side he is quite unable to extend the arm, but if passively extended he can flex it to a right angle at the elbow. There is no movement at the shoulder-joint. There is slight flexion, but no extension at the elbow. He can flex his fingers, but there is no grasp; he cannot extend them. There is rigidity at all the joints, especially the

No. 3724.

shoulder; this can be overcome without causing pain. The thenar eminence and the first dorsal interosseous are wasted. There are no tremors. On the right side the voluntary movements of the arm are all fairly good, but vary very markedly, especially at the shoulder, which after repeated movements becomes rather feeble. The movements at the elbow, wrist, and fingers are fair, but here again they are weaker after each attempt—especially the extension of the wrist. There is slight rigidity at the shoulder, more than at the other joints. Wasting is seen in the first dorsal interosseous, but less marked than on the left side. There is no tremor, and the muscular sense is not impaired. The patient is unable to sit up in bed. On the sensory side the patient describes a feeling of numbness in all his limbs. Objectively, sensation to touch, pain, and temperature are normal in the legs and arms. The plantar reflex is active and equal on the two sides. The knee-jerks are very active and equal. There is no ankle-clonus. The wrist- and elbow-jerks are obtained on the right side, not on the left. The vision on the left side is $\frac{1}{2}$ and on the right side $\frac{3}{4}$. There is no nystagmus and no diplopia. The field of vision in the left eye is contracted on the nasal side. In the right eye it is normal. Mr. Gunn reports that the left optic disc is "on the pale side of normal." The pupils are equal, and react to light and accommodation. All the other cranial nerves are normal. The patient complains occasionally of frontal headache, but no tender spot has been elicited. There is no irregularity of the spine. All the other functions are normal. The faradaic and galvanic reaction of all the muscles of the arms and legs is normal. Tremor occurring on making an intentional movement and subsiding when this is discontinued is the symptom which, of all others, is considered the most characteristic of insular sclerosis, and I suppose that if it be present in a typical form it is almost conclusive evidence of the disease. Nystagmus, also, is a symptom of great importance, though its frequent occurrence in cerebellar disease, Friedreich's ataxy, and in chronic alcoholism must always be remembered. The laboured articulation observed in Patient A. is also useful for purposes of diagnosis, but in my experience it is not often present. For the moment I will content myself with calling your attention to the fact that in Patient B. there is no tremor on intentional movement, no nystagmus, no scanning articulation—and present to you Patient C.

Patient C., a man thirty years of age, a widower, was admitted on Sept. 17th, 1894, on account of partial paralysis of both lower extremities and of the right arm. Seven years ago the patient was in the out-patient department complaining of numbness in the body and legs. At that time there was no loss of power, and he was able to continue his work. He also complained of numbness and tingling in the tips of his fingers. These symptoms sometimes ceased for weeks together. In August, 1888, the numbness was better but the legs were weak and his gait was unsteady. In June, 1889, it was noted that the right knee-jerk was exaggerated and there was ankle-clonus. The left knee-jerk was obtained with difficulty. The patient gave up his work in July, 1889, owing to the weakness in the right leg. At that time there was "slight anaesthesia of the left hand and foot, especially in the fingers and toes." In January, 1890, he was admitted into hospital with weakness of the right arm and leg. In July of the same year there was more weakness and stiffness. In March, 1891, the symptoms noted were headache, nausea (no actual vomiting), drooping of the right angle of the mouth, and a spastic condition of the right leg. The left optic disc was noted as being pale. In October it was remarked that he was much worse and much upset by the death of his wife. A note made in February, 1894, in the out-patient department shows that he had been slowly getting worse. It adds "There was no clonus. The knee-jerk was exaggerated. The patient cannot walk, but can move the right leg when seated in a chair." In March, 1894 he lost the use of the left leg completely in a day or two. Since then it has been getting stronger. The patient is a temperate man, and has been comfortably off. Previous to the time noted his health had been good, but he had been exposed to venereal disease and had suffered with a bubo at the age of twenty years. There had been no secondary symptoms. The patient's wife died three years ago. She had had no miscarriages. They had been married eight years and were childless. The patient's appearance is healthy, and he is well nourished. Mentally he is intelligent, and seems to be reliable. He is unable to stand. There is marked weakness of both legs, especially in the right. The

B

right leg cannot be lifted off the bed, the only voluntary power consisting in being able to flex the thigh and knee. The muscles of the leg are weaker than those of the thigh, especially the extensors. The foot is in the position of talipes equino-varus, and the toes can hardly be moved at all. There is marked rigidity at the thigh, knee, and ankle-joints. The left leg is also very weak, but shows more power than the right. The heel can be raised off the bed and other movements performed against very slight resistance. The thigh is stronger than the leg, and extension than flexion. Rigidity is present, but less so than in the right. The left upper extremity is strong. On the right side there is rigidity at the shoulder, elbow, and wrist-joints so that the various parts are kept in a position of flexion. All the movements of the forearm are weak, but especially that of the extensor group. The grasp is feeble, flexion of the forearm on the arm weak, and the action of the triceps moderate. The arm cannot be abducted except feebly, nor can it be raised beyond the horizontal position. The trapezius, serratus, and latissimus dorsi appear to act well. Both knee-jerks are exaggerated; the right more than the left. There is ankle-clonus on each side; on the right more than on the left. The triceps and radius jerks are increased on the right side. The cremasteric and plantar reflexes are normal, and the abdominal and epigastric not obtained. On the sensory side no objective disorder is found. Subjectively the patient complains chiefly of a gnawing pain in the right lower limb, starting from the hip, which comes on chiefly at night. It is not of a shooting character. There is no feeling of numbness anywhere, no pins-and-needles, or tingling. There is occasional frontal headache—no vomiting or sickness. He takes a long time to pass his urine and has to strain, with a feeling that some is left behind. He is always conscious of the act; it never passes involuntarily. There is no trouble with the rectum. The pupils, which are equal, act normally. Ophthalmoscopic examination shows that the left disc is slightly paler than the right. In each eye vision equals 3; Jaeger No. 3 at 12 inches. The fields are normal to rough estimation. For a few days, three years ago, he suffered from diplopia. There is none now. Note that in this case, again, there is no tremor, nystagmus, or affection of articulation. On the other hand, in both these cases a subjective sensation of numbness is described.

Patient D., a woman twenty-seven years of age, single, in domestic service, was admitted into hospital on Oct. 9th, 1894, with loss of power in the lower extremities. One day in May, 1893, without any previous warning, the patient noticed that her left leg dragged, and that she tired very soon. If she attempted to run she fell down. At the same time she found herself unable to lift things with the left arm. In spite of these symptoms she continued at her work, but was unable to walk any distance out of doors. The arm gradually recovered in the course of one month, but the leg has never got well, though the dragging has ceased. At the onset the left leg became numb; it felt to the patient like a log of wood; sometimes the whole leg tingled like "pins and needles." Since December, 1893, both legs have been weak, and often give way at the knees. After walking about 100 yards she is quite unable to move one foot in front of the other. After being ill for about three months she was treated by a medical man for "hysteria." Three months ago she noticed that she could not hold her water, the call was so rapid, nor could she check the evacuation of the bowels. A week ago she found that her sight was not good for doing fine work. There has never been any diplopia. Previous to the present illness her health had been always good, and had never been better than on the day when the weakness in the leg suddenly occurred. She had never suffered from influenza, and the catamenia had always been regular. There had, however, been a good deal of mental trouble at the time of her attack. She has always been comfortably off, has not suffered from exposure to weather, or sustained any injury by violence. The family history is excellent. At the present time the patient is a healthy-looking girl, well nourished, bright, and intelligent. There is no affection of speech. She can stand alone with her eyes open, but when these are closed she soon loses her balance, but shows no tendency to fall in any particular direction. She manages to walk alone, but is very unsteady and insecure. One leg is apt to stick in front of the other, and this nearly upsets her. She can cross one thigh over the other and raise herself from a sitting posture, but she cannot mount on a chair with either leg. In bed the movements of the lower limbs seem fairly well

performed, without obvious difference on the two sides. The feet are not dropped and the extensors of the feet and toes are fairly strong. There is slight rigidity in the lower limbs. There are no tremors. The movements of the upper extremities are well performed; no tremors are observed in them, and no rigidity. She can raise a glass of water to her lips without shaking it. On the sensory side there is no objective disorder. She complains of numbness and a tingling sensation over the whole of both her lower limbs. There are no pains, or girdle sensation, or headache. There is very slight ptosis of the right eyelid, not observed on a later examination. The pupils are equal and react to light and accommodation. By a rough estimation with upheld fingers the field of vision is normal. The vision right and left is 3; on the right side Jaeger No. 3 at ten inches; on the left side No. 1 at ten inches. There is distinct pallor of both discs, rather more marked on the right than the left, especially in the lower and temporal portion. There is nystagmus, of fine range, and rather slow in all directions, except downwards. It ceases when the eye is at rest. There is nothing notable in the other special senses, or in the thoracic and abdominal viscera, except that the heart shows a little irregularity of beat. There is no bruit, and there are no signs or history of cardiac failure. On Oct. 16th it is noted that there has been a great increase of weakness in the legs so that the patient is quite unable to stand, and cannot even raise her heels off the bed. In a few days this was recovered from, and she can now walk, though with difficulty. Again we find an absence of tremor or voluntary movement and of any peculiarity of articulation. But in this case there is nystagmus, which was absent in the two male patients.

Patient E., a woman thirty years of age, married, was admitted on Oct. 2nd, 1894, on account of loss of power in one upper and the opposite lower extremity. At the age of sixteen years the patient had an attack of headache and vomiting, and was in bed for a week. On recovering she noticed that at times attacks of powerlessness would come on in the right arm, so that things were dropped. These attacks recurred during a period of a few months, and then entirely ceased. She has never been able to write properly with that hand since then. Within the last few months she has noticed numbness occasionally in the right arm. About three years ago, when out walking, she had a sensation of "pins and needles" in the left foot, and the leg dragged a little. Soon after this weakness in the left lower extremity was observed, so that she had difficulty in going up and down stairs. In walking there was trouble in lifting the foot off the ground, and she often had to grasp objects for support. From that time the weakness has been gradually getting worse, especially after a confinement, but she has never been unable to stand. Since the onset she has often been troubled with numbness in the calf and occasional "pins and needles." There has never been any weakness in the right leg, and never any trouble with the bladder or rectum. The patient since eight years of age has been subject to headache, especially at the back of the left eye, and, according to her account, accompanied with drooping of the eyelid. For the last four years, since marriage, she has sometimes a tearing kind of headache at the back of the head, and a feeling on the vertex as though she had been struck by a hammer. There is no reason to suspect that she has had syphilis, and there is no family history of any nervous disorder. The patient is a fairly healthy looking woman, rather thin. She can only stand alone with difficulty and for a short time; she usually falls to the left. When walking she has to grasp objects to prevent her from falling. The left leg is dragged, and the toes scraped; the heel does not touch the ground until nearly the end of the step. There is a tendency to turn the sole of the foot inwards. As the patient lies in bed her left foot is rigidly in the position of talipes equino-varus; the big toe is hyper-extended and the power of flexing it is weak. All the movements of this limb are retained, but in much weaker form than on the right side. When sitting on a chair the patient cannot lift the left thigh over the right, or get up on to the chair by the left leg, or dorsiflex the left foot. She can raise herself to the standing position easily. The grasp on the right side is distinctly weaker than that of the left. Flexion and extension of the forearm and the movements of the wrist are also weaker. No difference is observed in the power of the deltoid, latissimus, or pectorals. The knee-jerks are brisk, especially the left. There is distinct ankle-clonus on the left side and a tendency to it on the right. The plantar reflexes are present. No

tremor is noticed in any extremity when at rest. No incoördination is to be observed when she attempts to approximate the index fingers or to touch the nose, or in raising a glass of water to the lips. An attempt to write results in the production of a perfectly unintelligible scrawl, the hand being at once seized with quick, small, rhythmical tremor; but when the right hand is supported by the left a legible though feeble signature is accomplished. On the sensory side nothing objective or subjective is to be noted. The functions of the rectum and bladder are normal; there is nystagmus; the special senses are apparently intact. On rough examination the field of vision is normal. There was nothing of importance in the viscera.

If we reflect for a moment on the endless variety of position occupied by the islets of sclerosis in this disease it appears remarkable that anything like a type can be found, and we can feel little difficulty in believing it as at least possible that cases like the last four, which present but few symptoms belonging to the classical form, may yet be examples of the disease. Let me call your attention especially to the last case, because it presents a feature which, in my experience, is perhaps one of the most characteristic of all in this disease, although comparatively little stress has been laid upon it by writers. I refer to the interval which elapsed between this patient's first symptoms at sixteen years of age and the affection of the left leg, when she was twenty-seven years. I do not think that there is any disease of the spinal cord, except insular sclerosis, in which you will find this kind of recurrence of loss of power in the same or another limb after one or more intervals of partial or complete recovery. Note what happened in the other cases. Patient A. two years ago felt a sudden weakness in the left leg and fell down. A feeling of weakness would occasionally be experienced after a long walk; but beyond this he was not inconvenienced for eight months, when weakness of the right leg and arm set in. Patient B. lost power in the right arm and leg, but recovered in six weeks and was able to go about his work as usual, and it was not till nine years later that his left limbs became affected. It was a year or more between Patient C.'s attack of numbness and his loss of power in the legs, and in the meantime he had been constantly at work. Patient D. lost power in her arm, but recovered it in the course of a month and resumed her work. The leg, which was affected at the same time, never completely recovered, although it became so much better that she hardly noticed any difficulty. Seven months after the first attack the other leg lost power. I will content myself with referring to this point in connexion with the five patients before us; but examples could be multiplied to a remarkable extent; indeed, if I am not mistaken, it is quite exceptional to meet with a case of insular sclerosis in which there is not a history of one or more often long-continued remissions.

Looking back I can remember a number of cases in which this recovery from more or less powerlessness for a time, to be followed by a return of trouble in the same or another limb, led me into temporary error of diagnosis, until the sequel, by displaying typical symptoms of insular sclerosis, cleared up the obscurity. When the remissions occurred in young females I used to fancy that the term "hysteria" could be satisfactorily applied to the case, whilst, if the patient belonged to the other sex, not a little suspicion of malingering would sometimes cross my mind. Subsequent experience, extending over many years, has pretty well convinced me that the view still widely held that a shifting of loss of power from one limb to another is characteristic of hysteria is an error which has arisen from cases of insular sclerosis being diagnosed as hysteria. As I said before, I do not think that there is any other disease of the spinal cord in which this feature is to be found, at least in the special circumstances by which it is marked in these cases. I am not forgetting that recurrence of symptoms, either in the same or another part, is very frequent indeed in syphilitic disease of the nervous system, and that in such instances there may be a more or less prolonged interval of exemption. It is necessary, of course, to bear this in mind, and in some cases there may be a certain amount of difficulty in the diagnosis.

There is not time on the present occasion to discuss fully our means of differentiating the two conditions. It must suffice to say that in very many instances of insular sclerosis (occurring, as the disease so frequently does, in young females of good social position) syphilis can be easily

excluded, that in the latter disease more or less complete paralysis rather than paresis is the rule, and that the effects of the remedies afford very great help, the power returning in insular sclerosis independently of any active treatment, whilst in syphilis the paralysis tends to become more and more confirmed until specific remedies are employed, when it usually begins very shortly to show marked amelioration.

I am disposed to think the condition of vision likely to afford much help in the diagnosis. Last year I adduced evidence¹ to show that some degree of optic atrophy was present in the course of forty-three out of a collection of 100 cases of insular (disseminated) sclerosis, and it was remarked besides that even when the discs presented no change some transitory amblyopia was to be found in a considerable number of cases of the disease. You will have observed that out of the five patients whom I have shown you no less than four are affected with amblyopia and present more or less pallor in one or both discs. It is especially to be noted that the amblyopia is very liable to remissions and recurrences in this disease, exactly recalling the peculiar feature already alluded to in reference to loss of power in the limbs. It would not be right to speak very positively on these points pending the opportunity of still more extensive observation; but I am certainly disposed to believe that the occurrence of paresis in one or more limbs, with spontaneous recovery, and recurrence of symptoms in the same or another part, together with amblyopia, accompanied or not by pallor of one or both discs, constitute a symptom-group which should hold a place in the diagnosis of insular sclerosis not second to that at present occupied by tremor on voluntary movement and scanning articulation.

An Address ON EXPERIMENTAL CRANIOTOMY AND DIAGNOSIS OF CEREBRAL ABSCESS.

BY PROFESSOR AUGUSTO MURRI, M.D.,
PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF BOLOGNA.
*Delivered on Nov. 30th, 1894, before the Lombard Medical
Association, and specially reported and translated
for THE LANCET.*

(Continued from page 12.)

ABSCESS of the brain, which when clinically considered seems to be an essentially unique morbid process, resolves itself into two varieties which differ utterly in diagnosis—viz., acute abscess and chronic abscess. Writers aiming at the unity of the process lose sight of the clinical side and do not bring into sufficient relief the practical differences which exist between the two varieties. What they say of the abscess applies chiefly to the acute form. Bacterial analysis might throw more light on the causes of the differences which are developed in the process of suppurative inflammation of the brain. At present, what we chiefly know is the intensity of the exciting causes; the duration of the process depends much on these. If a considerable cerebral artery is closed by an embolus; if a wound on the head causes disturbance, contusion, or hemorrhage in a zone of the brain; if a suppurative otitis media violently affects the bony substance and gives rise to a thrombus in the cranial sinuses, or excites inflammation in the adjacent meninges—the nutritive process of the cerebral tissues near cannot avoid deterioration, the pyogenic agents find a field well prepared, and their devastations are in consequence very rapid. But here, besides the rapidity of the disease, there arises another clinical distinction. These occurrences, being more intense, cannot easily happen without being perceived by both the patient and his medical attendant. Moreover, the succession of phenomena aroused by them is not so disconnected as to lose the evidence of their reciprocal relation and the unity of the process they reveal. Finally, even the reaction of the brain provoked by rapid and great intracranial changes is more evident and appreciable to the practitioner. If to all this we add that the rapid diffusion of suppuration causes fever, and even a special fever,

¹ Atrophy of the Optic Nerve as a Symptom of Chronic Disease of the Central Nervous System. Brit. Med. Jour., Oct. 7th, 1893.

as a phenomenon revealing the nature of the morbid process, then it is easy to comprehend how the clinical idea assumes a form so distinct that the diagnosis of acute abscess naturally follows.

When we come to the chronic forms of cerebral abscess the description and opinions of pathologists, inspired by the observation of such facts, no longer correspond to the facts themselves. In these the exciting causes are less intense or less apparent. It is one thing, for example, if an embolus from a pulmonary vein closes the artery of Sylvius, and another if pus penetrates unperceived into the brain by one of those narrow ways which lead there from without. The slowness of the latter is not only marked by the absence of disorders perceptible to the medical man and patient, but it also causes a slower succession of changes around itself; the surrounding tissues, not previously affected and less violently attacked, have time to organise themselves for the defence, and in time circumscribe with a solid barrier (pseudo-membrane) the hostile element (pus) which tends to destroy it. This mysterious faculty which the brain possesses of adapting itself to the most serious lesions as long as they are gradual has full opportunity to act completely. Thus it follows that from ignoring or forgetting the primary cause it seems as though no external cause exists; and here we have the idiopathic abscess, which is almost always chronic. Even where the primary cause is known, if it be not violent the process which succeeds follows with less rapidity, and hence the slight changes of the brain may not arouse perceptible functional disorders. Here we have the latent abscess or the latent period of the chronic abscess. The slowness with which brain alterations proceed proves that a length of time is required for their development, and here we see the abscess become chronic. The perception of these internal processes is often defective, as is frequently seen in the doctrinal works of pathologists and in the reasoning of clinical physicians, who write and think of cerebral abscess as though it existed only in the acute form. But the abscess exists also in the chronic, idiopathic, latent, or semi-latent form, and this, though less frequent than the acute, is by no means as rare as statistics would make us believe.

Acute abscesses caused by a wound or by suppurative otitis abound in the practice of the surgeon and the aural surgeon, and are less frequent in that of the general practitioner than the chronic abscess, which is, perhaps, the reason why this figures so seldom in surgical or aural statistics. This is as yet mere conjecture, but time will decide whether future statistics will prove it. Some clinical observations will, perhaps, serve better than pathological ones to show the most frequent difficulties encountered in the diagnosis of chronic abscess of the brain.

In June, 1892, a man thirty-two years of age entered the clinic. The only event in his life needing mention was a large scald in the arm occurring when he was four years of age. After this he had no other ailment except a lobar pneumonia at the age of twenty-six, and then enjoyed perfect health until 1891, at which date he fell from a height of about twenty-four feet, without, however, hitting his head; he fell on his feet and left side. This accident did not cause insensibility, but it produced a sensation of faintness, which some hours later was succeeded by another phenomenon—viz., certain clonic and rhythmic movements which lasted about two minutes without at all disturbing his consciousness. The phenomenon was repeated four or five times during the day, and was observable even in sleep, which was not disturbed by it. It has never ceased from this time. The patient has been unable to return to his usual work. It was only in the succeeding February that he was attacked by headache, especially in the neighbourhood of the right ear and forehead. He had, whilst perspiring, been exposed to intense cold. The pain was so violent that he was for several days confined to his bed. His medical attendant first ordered cold compresses and afterwards applied leeches to the head. Just as these remedies seemed to be succeeding he was again taken with convulsions, which for the first time caused him to fall and lose his senses. The attack was brief, but it left traces behind it; a most intense headache set in, which lasted a full month. The sight remained permanently dimmed. This attack was not repeated till May, and then another phenomenon ensued—i.e., diminution of power in the right arm. This, however, was not permanent. These two more serious crises, with loss of consciousness, were not preceded by aura, or accompanied by cries, foaming at the mouth, or biting of the tongue; nor were they renewed. Only during May a new disturbance presented itself, returning every day till June 6th. It was an intense tremor, which

began in the right arm and then spread over the whole body, lasting about ten minutes. On entering the clinic the patient complained especially of pain about the right ear and forehead, and of a mucous discharge from the nose. He was a man of finely proportioned frame and was well nourished, and his muscles were fully developed. The objective examination revealed no anomaly in the nervous system. The voluntary movements; the reflex actions, both superficial and deep; sensibility to touch, to pain, to heat and cold, and to electricity; and the psychic functions—were all natural. Only the organs of sense presented any anomaly. Researches into the discharge from the nose showed an atrophic rhinitis. The right ear distinguished sounds at a less distance than the left, and yet the ticking of a watch was perfectly transmitted by the bones of the face and cranium. The direct examination by Dr. Secchi led to the diagnosis of salpingo-tympanitis in the right ear. An ophthalmoscopic examination revealed the presence of a serious bilateral inflammation of the nerves of the retina with hæmorrhages. The patient suffered occasionally from a momentary clouding of consciousness (*absence épileptique*) which lasted for ten or fifteen seconds, and left behind it a confused memory of discomfort and increased headache. He spoke of giddiness and said that if he had been standing up he should have fallen; but this access always chanced when he was seated or lying in bed. The patient walked well and ate, digested, and slept like a person in health; neither pulse nor respiration offered the least sign of alteration, though observations were prolonged through fifty days. His temperature was always below normal. On the morning of June 2nd he went to the water-closet. Finding he did not return the attendant entered and found him with his head falling and his arms supine; his breathing had developed the Cheyne-Stokes rhythm, and a greenish liquid was oozing from his nose and mouth. He remained in a state of coma till his death at 2 P.M. Opening of the skull revealed the ordinary lesions dependent on increased intracranial tension; the convolutions were pressed together, the fissures being almost invisible; and there were numerous bloody stains on the meninges, which were softened in all the zones. The sinuses and veins were turgid, but without sanguineous coagulations. In the middle fossa of the skull, to the right, the dura mater was thickened and covered with pus and reddish-grey granulations; it was, however, easily removable from the osseous tissue, and its under surface had a normal aspect. In the right temporal lobe there was a purulent abscess which rested on part of the diseased dura mater; this, indeed, formed the inferior wall of the cavity of the abscess, which was as large as a walnut and limited by a false-membrane of great resistance. The cerebral tissue surrounding the abscess presented a white, softened aspect. This softened tissue reached the interior of the optic thalamus and extended behind as far as the occipital lobe. The ventricles were over-full of fluid and the cerebral substance was oedematous. There was nothing remarkable in the rest of the cranium, there was no trace of (previous?) fracture in the bones of the base, and no necrosis. The temporal bone, which was especially examined, was in a normal condition. Thus, the post-mortem examination confirmed the clinical judgment, which had been that of cerebral abscess; but we must allow that this correspondence of the clinical hypothesis and the pathological fact could not even now be proved by valid arguments. The symptoms already referred to prove that there was a morbid process going on in the brain, but did not demonstrate an abscess. No wound had directly injured the head, which had received no external lesion. Admitting that we must believe in an internal lesion (due to laceration, hæmorrhage, or otherwise), why may we not have believed that this proceeded from a tumour rather than from an abscess? External lesions being absent, where are we to look for the cause of suppuration? Would not the constant absence of fever, too, point to the diagnosis of tumour? And would not the ever-progressive course of the disease still more favour it? I leaned to the theory of abscess because there were no phenomena of infection, nor was there paralysis of the cranial nerves, but I confess that the argument was more lucky than sound. Therefore I recommend my pupils to doubt—doubt much and doubt often—because my own arguments in favour of abscess were very uncertain. Indeed, I have myself seen many intracranial tumours which, like this abscess, existed without phenomena of infection and unattended by paralysis of the cerebral nerves.

Even in cases where the diagnosis is fortunate the physician

who declines to affirm more than reason concedes must often stop at a diagnosis of greater or less probability, because he finds conjoined some phenomena which indicate one thing and others that assert the contrary. I always inculcate on my students this forced resignation; but the difficult labour of prudence, diffidence, and circumspection which is learned in the schools is quickly frustrated by the reading of books that are deservedly held in great esteem. Even a most prudent master, such as Leube, more studious of the difficulties of diagnosis than any other, continues to teach¹ that the diagnosis of subacute or chronic cerebral abscess is, on the whole, easy, and he gives as the most important indication of abscess intermittent fever associated with rigors, and he also attributes greater value to the absence of the optic neuritis and etiological considerations. In this way we should diagnose a tumour, because there is no fever and the congestion of the papillæ is evident. Certainly I should not merit blame, as I deserve no praise, for giving greater weight to opposing arguments; but, to be sincere, we must own that mistakes may be made in both ways.

Not being able to allow that an injury without external lesion generates a cerebral abscess, especially as the injury (in the case above quoted) was not on the head, the anatomical section favoured the following interpretation. Falling on his feet from a great height, the patient received a cerebral contusion in the region of the temporal lobe. To this may be attributed as indirect phenomena the muscular contractions which succeeded the fall. In fact, the circumstance that suppuration had extended to the meninges confirmed this idea, although it is known that chronic abscesses of the brain, when not caused by wounds, are almost always deep and covered with a stratum of nervous substance which divides them from the meninges. Körner has demonstrated that in abscesses due to caries the stratum of the brain which divides the pus from the solid matter is very thin and altered in structure; in this patient, however, there was absolutely no trace of caries of the bone. Nor could the stimulus to suppuration have been from the injury, without external lesion; this stimulus, which changed a cerebral contusion into a chronic abscess, possibly came from acute otitis which had not suppurated. At first sight this hypothesis seems to be an unlikely one, but if we reflect that excellent conditions exist in the ear for the generation of pus, and that the channels of communication between the ear and the brain are many and easy, it is not impossible to comprehend how a suppressed otitis might emit germs which enter the brain and generate a suppurating process. Oedema due to the abscess, acute venous stasis under the strain of evacuation, or perhaps some convulsive attack caused sudden death by the rapid increase of cerebro-spinal fluid and by the great venous stasis and bleeding of the meninges which followed. Such a genesis is so rare that probably my interpretation will seem to many to be not well demonstrated. But I have chosen precisely this case in order to prove how obscure the etiology of abscess on the brain can be even where the common indications of the causes are not absent. It is clear that in a path so obscure it is easy to err in our interpretation; yet the clinical physician is obliged to anticipate, although unprovided with the knowledge which necroscopy furnishes.

I do not say that we can never predict the succession of events which give rise to some of those cerebral abscesses not caused by wounds; indeed, I should like to submit a case in point, which is admirable for its clearness of interpretation. The diagnosis could be made with perfect security. The case was one of a young peasant from Imola aged twenty-one years. He entered the surgical clinic at Bologna on Aug. 17th for an empyema on the left side. He was treated by aspiration and washing out of the pleura. This youth had never presented symptoms of injury to the cerebral functions when on Aug. 25th he was suddenly seized with vertigo and loss of consciousness and fell. He was standing at the time. He did not recover consciousness for half an hour. After another half-hour the attack was renewed, accompanied by convulsions in the upper limbs. Three hours later a third attack supervened, and he remained insensible till the following day. During the succeeding days all seemed to return to its normal state, but on Aug. 30th he was again attacked by convulsions, no more diffused, but limited to the head and right arm. Another attack, yet more serious, seized him the day after; all the right side of the body was shaken by tonic and clonic contractions, the mouth was filled

with froth, and consciousness was again entirely lost. This also passed off, and it was observed that the lower part of the face and the right limbs were paretic. The attack was renewed in the evening of the same day. His speech began to alter on Sept. 2nd and by the evening of the 5th he could no longer articulate, though the epileptoid convulsions did not return. He had at first a slight irregular fever, but this afterwards ceased. From his entry into the clinic on Sept. 14th till the time of his death on Nov. 10th his temperature varied very slightly above or below normal. It would be useless at present to refer to the data obtained by examination of the thorax. I will only remark that, besides the pleurisy, the organs of the chest and abdomen afforded nothing worthy of note. The nervous system presented paralysis of the jaw and absolute paralysis in the upper limbs and incomplete paralysis in the right leg. The passive movements of the arms were limited by a certain resistance of the muscles; whereas the lower limbs were lax, and even voluntary movement of the leg from the thigh and foot from the leg was possible, though weak. Muscular power was diminished also in the left arm. All the reflexes were normal; but those of the periosteum were deficient, as they only existed in the right ulna. Also the different forms of sensibility were perfect, except the muscular sense on the right side, where the patient could not distinguish weights which were quite perceptible to him on the left. The sense of the position of his fingers was also a little obtuse on the right. The special senses were normal. In the course of October, however, the sense of pain was less acute on the right than on the left side; at a later period, on the contrary, it became more acute. There was distinct aphasia. The patient could pronounce some words, but with difficulty. The tongue deviated to the right. He had no convulsive attack till Nov. 1st, when he had one without losing consciousness. It lasted ten minutes, during which all the muscles of the right half of the body displayed clonic jerks. Headache and vomiting followed during the succeeding days. On Nov. 10th, becoming weaker by degrees, the patient had two attacks of insensibility without convulsions. These were followed by a period of comparative lucidity; but in the evening intermittent tetanic spasms seized him, which lasted till 3.30 A.M. of the 11th, when he died. On that day no movement was evident except a certain degree of contraction in the toes. The ultimate loss of consciousness took place four hours previous to his decease. The pulse and respiration presented nothing remarkable, nor did the urine. Not till the evening of Nov. 10th did the temperature rise for the first time in a marked degree, so much so that at the time of death it reached 42.7° C. (108.8° F.). On the cranium being opened the sinuses and meninges showed nothing striking. The left frontal lobe appeared to be more prominent and rounded than the right, and a sense of fluctuation was observable in the elevation of the first and second frontal convolutions on the left. On introducing a syringe into the second convolution there issued about 50 grammes of purulent matter, greenish, dense, and fetid. A transverse section of the brain showed that the cavity of the abscess reached nearly a centimetre above the roof of the left lateral ventricle. This cavity was roofed in by the subcortical layer, and downwards gradually enlarged to almost a centimetre above the level of the corpus callosum. It began in the anterior portion of the frontal lobe and extended through the centrum ovale to beneath the convolutions of the motor area; the shape was that of an ellipse, of which the greatest diameter parallel to the median fissure was 7 cm. long, the smallest diameter being 3 cm. Its greatest depth was in front; the cerebral substance was softened at the back. The parietes of the abscess were formed by a thin stratum of rosy colour, of greater consistence than the white substance, and covered with a greenish-yellow membrane. This membrane was detachable and was of the capacity of a large hen's-egg. There was nothing in the rest of the brain except three or four branching grooves of a vivid red colour in the caudal nucleus on the left, caused by the congested bloodvessels. Senator² and Drummond³ have made similar observations; but the commencements of the cerebral phenomena were not in their cases as marked and serious as in my patient. In this case the sudden, complete, and prolonged loss of consciousness, followed on the same day by unilateral epileptoid attacks, showed that from one moment to another the conditions of

³ THE LANCET, July 2nd, 1887.

the brain were changing, and this could not happen except through disturbance of the circle of Willis. Now in the case of an empyema one is forced to the supposition of an embolus of the left Sylvian artery, because the absence of all paralysis at first and the return of convulsions on one side in a young man aged twenty-one, whose heart and blood-vessels are healthy, peremptorily exclude suspicion of hæmorrhage and thrombus. In the cases of Senator and Drummond, the commencement of the disease being more gradual, the elimination of the hypothesis of a tumour was less absolute than in mine, where the reason for the elimination was evident. The following symptoms served to demonstrate that we were not treating of a mechanical embolus, but of an infective one. The collateral blood-supply must have sufficiently nourished the organ, because the patient passed four days without convulsions, paralysis, or injury to the senses. Consequently the symptoms which supervened showed that there was being developed in the same cerebral region, from the first violently injured by disturbance in the circle, an irritative and destructive process. This must have been excited by some agent from the embolus which, detached from a pulmonary vein, had lodged itself in an artery of the brain. No possible objection could be made to the logic of this physiological interpretation of the morbid phenomena, and hence the clinical diagnosis was quite exact. But how rare this desirable evidence of facts is in practice. More often the chronic abscess remains unsuspected, or we may suspect without being able to prove it; or else an abscess is believed to be where none exists. Every clinic could give proof of this assertion. Here, however, are the proofs which I have to give. I will begin with the history of a case which I observed in 1879, and which I left with the undecided diagnosis of "cerebral tumour or abscess," so old are my opinions on the subject.

The patient was a foundling five years of age. His short life as given by the nurse contains the important fact that between his sixth and eighth month he had five attacks of eclampsia. He suffered from rickets, and developed slowly; but later he appeared to be healthy and intelligent, although he had in the right leg a sinus which had opened two years before he entered the clinic. Besides this, a cicatrix was found in correspondence with the right parietal protuberance, which two years before had been in a state of suppuration. This wound on the head assumed some importance from the fact that the little patient, after being well for three years, once more had convulsions. During their occurrence the boy preserved consciousness and complained of pain and weakness in the left limbs. The attacks were only repeated a few times and then ceased. But not long after he began to suffer from a constant and severe headache; then, in February, 1879, he had fits of sickness, hesitated in his speech, and showed a deviation in the angles of his mouth, accompanied by a flow of saliva. At this juncture he was brought to the clinic. He had scarcely entered when he had a convulsive fit, which I find thus described in the history of the case: "All the muscles of the right side showed clonic contractions, especially the flexors of the limbs; the head was turned to the right, the eyelids half closed, eyes fixed and immovable; pupils dilated and not sensitive to light; pulse 120, respiration 40 to the minute. There was complete insensibility, and no impression could be made on the sensory nerves or special senses. This state of things lasted ten minutes, when the contractions became weaker and ceased; the breathing calmed down, and consciousness began to return. Then the same contractions returned, lasting the same time as at first, but on the left side instead of the right. This ceased and began again on the right. This alternation of convulsions continued for four hours, after which the child became quiet and slept profoundly. The next day, Feb. 9th a slight paresis of the left side was observed. There were bilateral mydriasis of the pupils and internal strabismus in the left eye. Sensibility was normal and intelligence tolerably preserved. There was nothing remarkable in the physical signs of the organs of the thorax and abdomen. The patient had no headache, but he had fever, which proved to be intermittent, with a minimum of 36° C. (96.8° F.) and a maximum of 39.2° C. (102.5° F.), though it was not often so high." Things went on thus till Feb. 23rd. Then an increased tendency to sleep was noticed. On the 27th another convulsive attack ensued, lasting twenty minutes. It is described in the notes as follows: "First of all the cheek flushed very red, then the breath became slower and deeper, the left arm became rigid in flexion, the right arm was affected, but the hand was still flexed. This lasted more than two minutes,

and then clonic contractions began in the left leg, which afterwards extended to the arms and diaphragm. The eyes were fixed; the pupils at first were dilated, later narrowed, and were insensible to light; there was complete unconsciousness." On touching the left limbs one perceived a slight tremor in the tendons. At length only a tremor in the left arm remained, and then complete stupor set in. In this state the temperature of the left temple was 32° C. (90° F.) that of the right being 33° C. (92° F.). The next day extreme and painful irritability of the whole body was noticed, especially on the right side. It was enough to touch the child ever so slightly, and he complained in spite of a partial state of consciousness; indeed, this lapse of sensibility constantly increased till death ensued on the morning of March 4th. All the functions of the nervous system were diminished, but on the eve of death a convulsion of less intensity took place. The respiration maintained its regularity to the last at 18 to 20 the minute. The pulse during the whole period of our observations varied between 120 and 140, except during the last hours, when it became less frequent. The temperature, which had been that of intermittent fever, gradually fell on Feb. 26th to 35.5° C. (95.5° F.), on Feb. 28th to 34.8° C., on March 1st to 34.5° C., on March 2nd to 32° C., and on March 4th to 25.3° C. (78° F.). The urine was normal throughout. It is not known whether the child had ever suffered from a wound on the head, but it is certain that he had a suppurative process in the parietal region, and, his being a boy and a foundling, we may reasonably suppose the origin of this suppuration to have been a fall or an unperceived blow not revealed to the physician. As, moreover, an intracranial process, especially a cerebral one and of the left hemisphere, cannot be doubted, the hypothesis immediately arises of an abscess in the brain caused by a wound. What arguments can be opposed to this judgment? As far as I see, only this—that the chronic process in the left half of the brain might be a tumour. Usually a collection of encapsuled pus of old date, has less expansive power than a neoplasm, hence the compression, which is resented by the tissue of the brain, is less in the abscess than in the neoplasm. It is equally true that usually cerebral abscess is found in the temporal lobe or in the cerebellum, and hence the indications of injured or diminished functions in the corresponding cerebral zone are either less distinct or absent altogether, for the functions of these two zones of the skull are little perceptible, if at all. These differences in the pathological process ought to bring some diversity into the symptoms provoked by them, for it is not the inner nature of the pathological process, but the physical qualities of its products and their seat which constitute their condition and most influence the genesis of the symptoms. An organ so wonderfully intricate and mysterious as the brain might be compared to a keyboard. Every key ought to produce a particular sound, and no other, whether it is pressed on by an abscess or a neoplasm. Hence the sound produced by one or the other may be—and, in fact, is—precisely the same.

Pathology certainly shows that the mechanical process of chronic abscess is frequently so slow and often so partial as to give no special phenomena. Hence there must always be a certain generic difference between the effects of one process and those of the other. But (excuse me if I insist too much on this point) when we come to facts, of what value are general principles? When a chronic abscess assumes great expansive force, and lies outside the temporal lobe and the cerebellum, where do we find arguments to distinguish it from a tumour? And when a tumour has a weak power of expansion or of compression, and is situated in the cerebellum or the temporal lobe, what reason have we to distinguish it from the commonest chronic abscess? The error is almost fatal. It is true that etiology sometimes assists us, for an injury on the head may favour the development of an intracranial neoplasm; we might find otorrhœa in one who has only tubercles in the brain, but a bronchiectasis or an empyema excludes the idea that a glioma or sarcoma is being developed within the cranium. Jansen has seen a patient who suffered from otitis with a chronic cerebral abscess, but this was not caused by the otitis, but by lesions in the thorax. Hitzig saw a man twenty-nine years of age who for sixteen years had suffered from otorrhœa, and had besides received a severe blow on the head, both being causes of abscess. Yet the patient had a cerebral tumour.

There is only one phenomenon of abscess on the brain

which we know to be connected with the nature of that morbid process and does not belong to the neoplasm—viz., fever; but those who affirm that this symptom of cerebral abscess is very frequent or constant, and this I will prove. I now wish to note the inverse facts, which consist of the existence of fever without the abscess. It happened thus in the little boy of whose case I have still to give the anatomical results. He had an intermittent pyrexia, which was an argument in favour of abscess and not of tumour. Instead, this is what we found: considerable internal hydrocephalus and abundant gelatinous exudation over the cerebellum, the pons, and the chiasm of the optic nerves. In the Sylvian fissures, along the vessels, were several minute grey granules (tubercles). The right hemisphere of the brain seemed to be larger and more consistent than the left. Incision revealed a neoplasm the size of a pigeon's egg, spherical in form, yellowish in colour, fibrous, and of homogeneous aspect. It was situated beneath, outside, and rather behind the optic thalamus, precisely over the inferior horn of the right ventricle, which, from the pressure of the tumour, was reduced in the centre to a mere narrow canal. The histological examination demonstrated that it was a sarcoma. There was nothing remarkable in the rest of the body except the mesenteric glands, which were swollen, hard, and yellow. A very few yellowish nodules were found in the right lung. It was then easy to reconstruct the facts. All the old phenomena and many recent ones depended on the sarcoma; but the principal indications (such as peripheral paralysis of the cranial nerves, slackening of the pulse, and coexistence of tubercles in other parts of the body) being absent, it was impossible to foresee its existence, because vomiting, headache, and coma seemed to be nothing more than an increase of the preceding disease, while fever could only be connected with the pre-existing endocranial process, and, therefore, the diagnosis would point towards abscess and against tumour.

In the same year (1879) there also entered the clinic a lad aged fourteen years. His father had died from tuberculosis; his mother still lived, but she had lost three children in infancy, and only this one remained. Her health was not good; for some years a feverishness, cough, and sanguineous expectoration had given cause to fear that she suffered from the same disease from which her husband died. At four years of age the boy had suffered from typhoid fever, to which was added a purulent discharge from one ear. This discharge was not continuous, but had with intervals lasted till his sixth year. Since then it had never returned, so that his mother had forgotten on which side it was. Excepting this, the patient had never had any other illness beyond a few headaches and bleeding at the nose which from time to time troubled him, especially of late. Fifteen days before he came to us the headache was renewed, and this time, besides being more intense, it did not cease as at other times; in fact, it increased in violence and was accompanied with sickness, intolerance of light, and noises in the ears. It was the first time that need was felt of medical aid, but the treatment which was advised did not prevent the boy from constantly growing worse. The least noise worried him; the headache, sickness, vertigo, and obstinate constipation made such an impression on the mother that she decided to place her son in a hospital. We found him to be a weak-looking lad, with ill-developed bones and muscles, and with every sign of anæmia. He had a suffering aspect and strained eyes. Inspection and sounding and tapping on the skull revealed nothing, nor did the examination of the external organs of hearing. The abdomen was retracted, and the trapezius, sterno-mastoid and pectoral muscles had a slight tonic contraction. Pain was felt on pressure of the back of the neck. The tongue deviated slightly to the right. The phenomenon of the *tache meningitique* was clearly perceived; there was nothing else abnormal in the nervous system. The physical examination brought to light the existence of a pulmonary consolidation in both apices, but without augmentation of bronchial secretions. The patient entered the clinic on Nov. 6th. In the subsequent days it was noted that the boy, although intelligent and possessed of memory and speech, was apathetic, could not sleep, and was troubled by light or the slightest noise. The sickness and contractions of the same muscles continued. Ophthalmic examination revealed a slight double neuro-retinitis. All the cutaneous surfaces became hyperæsthetic and were covered by transient red marks. Although well covered, the patient was very cold. The apathy increased, and by Nov. 9th he passed his evacuations in bed without calling the nurse. All the flexor

muscles of the limbs were a little contracted; the right pupil was less sensitive to light than the left; and the lower part of the face showed less power of movement. The pulse, respiration, and temperature had been normal till now, but on the evening of the 10th the temperature was 38.6° C. (100.50° F.), the pulse 120, and the respiration 30. A falling of the left upper eyelid was also observed. During the following days the patient emitted a continuous moaning cry. The outward movements of the right eyeball were very limited. The head was rigidly retracted. The breathing was irregular, and the temperature then rose above 40° C. (104° F.), but even this was irregular. The pulse, on the contrary, remained regular to the last. Thus, growing worse without any other noticeable symptoms, the patient died on the morning of Nov. 4th. He was the only surviving son of a father who had died from tuberculosis and a mother probably phthisical, and it appears that, with the apices of the lungs consolidated, he must have died from tuberculous meningitis. The paralysis of the facial and of the right abductor branch of the motor oculi nerve and of the hypoglossus, though not intense, pointed to a basal process. The headache, final fever, irregular breathing, and continuous moan, the falling in of the abdomen, the meningitic *tache*, and the rigidity and pain in the nape of the neck—would have all aided the physician if he had chosen to make a diagnosis of tuberculous meningitis; instead of which no tubercles were found even in the lungs, which only showed a chronic process of interstitial fibrosis, especially on the right. On opening the skull the dura mater was found to be swollen and opaque everywhere, and all the meninges were much congested. On the base of the cranium was a gelatinous yellowish exudation of recent date, with no trace of tubercles in any part. All the ventricles were much dilated. Pus was seen issuing from the Sylvian fissure, and was found to proceed from an abscess caused by meningitis. The report is as follows: "The left centrum ovale displays a distinct and diffused white softening; also the anterior two-thirds of the corpus striatum are softened; the posterior third is gone, and is replaced by a collection of dense greenish pus which occupies the anterior horn of the lateral ventricle on the left, and, extending by irregular ways towards the base of the brain, enters the orbital convolution and the fissure of the Sylvian artery. The cavity is lined by a thick, hard, pseudo-membrane, which, however, is wanting in the inferior extensions. The opened skull and dissected brain would seem to indicate that the otorrhœa had determined the abscess to the centrum ovale, the abscess having thus remained latent for many years without injuring the intellectual development of the boy, and perhaps manifesting its noxious action by anæmia and weakness of the organism. After many years of quiescence, without any known cause, pus commenced to make its way towards the base, basilar meningitis ensued, and with it all came the final scene. That the process had been in existence a long time was proved by the chronic hyperplastic pachymeningitis and the thick point of origin of the abscess—although, according to Köner's observations, no abscess from otitis could ever have lasted more than a year and a half. But would it have been possible to foresee everything? There had been a suspicion of otorrhœa, but it had entirely ceased for the space of eight years. If this etiological criterion led to the idea of an abscess, why did the tuberculosis of the father and mother and the death of all his brothers not lead to the diagnosis of basal tubercular meningitis?"

The light furnished by these etiological deductions seems to fail us as soon as we apply it to a solid fact. Thus, one who falls upon his feet or his thigh, but who receives no blow or injury to the head, cannot be supposed to be affected with cerebral abscess; yet, nevertheless, he may die from it; while one who shows traces of a suppuration of the tissues which surround the bones of the cranium would lead to the belief that he was suffering from an intracranial abscess, and yet may die instead from sarcoma and encephalic tuberculosis; and, again, one who for eight years has recovered from otorrhœa, and who seems destined to die from tuberculosis, succumbs to suppuration of the brain. Sometimes the necroscopic examination of these patients offers a real surprise. Fortunately, the latency is seldom complete, or, at any rate, ceases to be so after a certain time. The physician can then hazard a suspicion. He must know that a chronic abscess, as the account of the case just related shows, may present the symptoms of a basal tubercular meningitis, but often proves to be the contrary. No diagnosis, however thorough, is enough to distinguish in

some cases between these two processes, which nevertheless, both in nature and position, differ so widely. As a rule the clinical student must remember that the chronic abscess, of itself, has few or no morbid manifestations; but that it shows them in certain developments, such as meningitis, the penetration of pus into the healthy brain tissue, the breaking of the abscess into the ventricles or under the meninges, extensive softening, &c.; but in the case of meningitis preceded by some sign which denotes the chronic abscess, as happened in the last-mentioned case, the diagnosis of the abscess may be made, as we made it, although the final symptoms may be precisely those of basal meningitis. Sometimes, however, the contrary occurs—that is to say, a tubercular meningitis resembles the abscess so much as to prevent any other conclusion. I know that the pointing out of a difficulty is not so good as showing the way to overcome it; yet it is undeniable that the more we admit the possibility of a diagnostic error, the more keen we become to avoid it.

(To be continued.)

AN ABSTRACT OF

A Lecture

ON

THE CONDITIONS OF CURE IN CANCER, WITH ILLUSTRATIVE CASES.

Delivered at the Cancer Hospital, Brompton, on Feb. 23rd, 1894,

By HERBERT SNOW, M.D. LOND., &C.,

SURGEON TO THE HOSPITAL.

[THE lecturer began by quoting, as an example of the ideas current even among the more educated classes upon the above topic, a phrase recently uttered at a public function by an eminent bishop of the Established Church: "Every-one knows that who once has cancer always has cancer." Pointing out that the popular sense of this word as synonymous with "malignant disease" coincided with the only plausible scientific theory which accounted for all the phenomena—viz., that of autositic cell reversion—he stated that the operating surgeon of the present day really claimed the power of permanently eradicating the various lesions known as "malignant," provided only that certain easily fulfilled conditions were placed within his grasp; and that when he failed, the causes of ill-success were now clearly understood in a manner impossible to the practitioners of the preceding generations. He showed that cancerous disease nearly always produces death by reason of the auto-infective qualities acquired by its cell elements and their mechanical transmission to distant parts; then discussed the obstacles to surgical cure presented by the different species in the ascending scale of complexity, beginning with rodent ulcer and ending with that form most closely identified with the popular conceptions of "cancer"—viz., carcinoma of the female breast. He continued as follows:]

Rodent cancer or Rodent Ulcer is the "least cancerous of cancers," as showing in its tardiest and mildest degree the "progressive tendency to death," and as being totally devoid of auto-infective phenomena in the shape of metastatic deposits. Though sometimes loosely used, the term correctly denotes only cancer of the short hair follicles, which is generally found in or near the lower eyelid, microscopically consisting in an aberrant reproduction of hair-follicle structure. As there are no secondary offshoots, the lesion is readily extirpated by knife or caustic within the first eighteen months or two years of inception. [The case of an officer thus operated on in 1885, and dying at the age of ninety-six in 1893 without recurrence, was here referred to.] At a later stage cure is impeded by the proximity of numerous bony structures covered by periosteum, a tissue speedily prone to malignant infiltration of any kind. Next ranks Epithelioma, the cancer of the epithelial cells, coating, skin, or mucous membrane, clinically differentiated from Carcinoma, the cancer of secreting

glands, by the important point that the metastatic particles are arrested by the adjacent lymph glands and only very rarely reach the bloodstream. Hence radical extirpation is effected by the removal of all the dangerous glands near simultaneously with that of the primary lesion, provided that this removal takes place before the relatively late stage of enlargement. For practical purposes three stages of growth in secondarily implicated lymph glands must be insisted on: (1) one of insidious deposit not recognisable by any symptom; (2) one of tenderness on pressure without enlargement; (3) one of increase in bulk. Each of these occupies at least a fortnight, often more. The track of infection along lymph glands is always definite and susceptible of accurate prediction; the fact of infection having taken place must always be assumed after the lapse of a certain time, varying with the site. To wait till glands enlarge before proceeding to their excision is usually to sacrifice the patient's life, as by that time still more distant organs of the lymphatic system will have reached the preceding stages. Thus, in epithelioma of the Lips the "infection path" lies through the submaxillary lymph glands situated at the anterior edge of the salivary gland similarly named; and on an average, secondary deposit takes place here within six months, frequently sooner. Hence it is rarely permissible to extirpate a labial cancer without synchronous dissection out of these latter, whether enlarged or not. The 38 per cent. of cures ascribed by a popular author, on the faith of German statistics, to a simple V-incision without attention to these glands is, in my opinion, vitiated by the obvious inclusion of non-malignant cases in the figures cited. On the other hand, in the Tongue the infection extends with far greater rapidity, always within six weeks, often in half that time. The dangerous glands are also the submaxillary in cancer of the anterior two-thirds: in cancer of the posterior regions, the cervical, just behind the angle of the lower jaw. The following cases exemplify the principles of treatment; it is not thought necessary to cite any affecting the lips or integument.

CASE 1. *Epithelioma of the tongue.*—A woman aged sixty years had an ulcer of four months' duration situated far back on the right edge of the tongue and having indurated edges; also lancinating pain shooting into the ear for several weeks together, with slight enlargement and tenderness of the right submaxillary lymph glands. Wide excision of the sore, leaving the bulk of the tongue intact, was done with the thermo-cautery, the glands being dissected out by submental incision. The operation was performed in April, 1886, and the patient was in good health (no recurrence) in January, 1890, when last heard from.

CASE 2. *Epithelioma of the tongue.*—A man forty-six years of age was admitted into the Cancer Hospital, Brompton, with a typical cancerous sore one inch from the tip of the tongue on the right side, which had been present for three months. It had an excavated base, with livid, hard, everted edges, and there was darting pain. Half the tongue was excised, with the corresponding glands in the pre-enlargement stage; the microscope revealed the characteristic features of epithelioma. This was done in June, 1886; the man was not seen again till March, 1891, on which occasion he reappeared on account of an attack of eczema; he was otherwise free from disease.

CASE 3. *Epithelioma of the tongue.*—A man sixty-five years of age had a prominent fungating livid sore half an inch in diameter situated at the posterior margin of the left half of the tongue. It had existed two and a half months; there was neuralgic pain darting up to the ear; no gland enlargement was present, but there was slight tenderness at a spot below the left angle of the jaw. The entire organ was removed, together with the glands at the site indicated. Under the microscope the usual globes *épidermiques* &c. were seen. The operation was performed in April, 1891; there has been no sign of recurrence up to the present time (January, 1895).

CASE 4. *Epithelioma in the floor of the mouth.*—A man forty-four years of age had suffered from a slight ulceration of the frænum for one year caused by a fish bone; he had felt pain for eight weeks only. The sore was very vascular, with indurated base and edges at this spot, involving the gum. On the right there was a cluster of enlarged glands the size of beans; those on the left side were tender, just beginning the enlargement stage. The tongue being threaded and held out of the way, the diseased part was freely excised by the thermo-cautery, the periosteum of the lower gum

being well cauterised at the same time, and the glands on both sides dissected out. This was in October, 1892. In February, 1893, a gland the size of a horse-bean, at the edge of the mylo-hyoids in the middle line, was removed. There has been no recurrence (December, 1894).

In the rectum and uterus operative surgery can, of course, deal only with the primary lesion. Malignant disease of the former organ (Cylindroma) fortunately develops slowly and seldom infects lymph glands or liver for a twelvemonth from inception. Hence free excision within that period should suffice. The patient whose case has been cited,¹ and which was one of special difficulty, still remains in the best of health; here a bleeding pulpy mass, of from one to two years' duration, projected into the gut from a part of the anterior wall so high that its uppermost limit could be touched only under anesthesia; the age at the date of the operation (May, 1890) was seventy-five years. This illustrates a general rule that malignant tumours growing without hindrance from a free surface are less prone to infect the glands than those bound down by dense fibrous tissue, such as the familiar breast scirrhus. Cancer of the uterine cervix (usually carcinoma, less often epithelioma) must be dealt with within eight weeks; otherwise recurrence will quickly ensue by way of the lymphatic plexus in the vaginal submucosa. Supra-vaginal amputation is the treatment; as the disease to the last often advances no higher than the internal os, and as the "infection path" lies in the direction indicated, hysterectomy should be reserved for late cases, and for disease within the uterine cavity. In that of rapidly recurring carcinoma, high up in the cervical canal, diagnosed within six weeks, and extirpated by escharotics,² the patient still remains well. The date of operation was July, 1883.

With malignant developments of the connective tissues (true sarcoma) a distinct series of clinical phenomena is encountered. There is here no infection of adjoining glands, per the lymphatics; if any such not in contact with the tumour are found diseased this is a sign of diffusion by the blood, and is associated with metastases also in the viscera. To eradicate, removal must therefore take place before cell particles have passed into the blood current. Sarcomata of the long bones should be treated by amputation at the proximal articulation; in consequence of the receptive qualities of their marrow, and its intimate association with the circulation current, the operative surgery thereof, which has hitherto generally neglected this precaution, offers far less favourable results than of the short or flat bones. Within the mamma and elsewhere connective tissue growths are commonly intra-cystic or encapsuled, a fact which tends greatly to delay the advent of blood infection.

CASE 5. Recurrent spindle-celled sarcoma of the lower jaw.—A man fifty-one years of age appeared at the Cancer Hospital, Brompton, with the body of the lower jaw at the symphysis greatly thickened by a hard nodular mass projecting inwards under the tongue, and where free of the bone, about one inch in diameter, filling all the front part of the floor of the mouth. The glands on both sides were infiltrated by contiguity and blended with the preceding. A previous operation had taken place three months since. Free removal of the tumour with two-thirds of the bone was effected in November, 1886. The microscopic appearances were as above. No recurrence had taken place in July, 1893, when the patient was last seen.

CASE 6. Spindle-sarcoma of mamma recurrent after two previous operations; cure.—An unmarried woman fifty-three years of age was admitted into the Cancer Hospital, Brompton, on Oct. 10th, 1884. Her medical attendant had previously performed two operations on the right breast, the site of which was occupied by a large scar. Under this there was a prominent tumour as large as a child's head, together with several round bosses, two of which fluctuated, one being of stony hardness. The total duration of the disease was six years, but there was now rapid increase, a dull aching pain present daily becoming more severe. Excision was performed, the axilla being untouched. A mass of cysts was removed, containing abundant embryonic tissue microscopically identical with that of an ordinary spindle-celled sarcoma. In December, 1893, the patient was in good health, and there had been no return.

CASE 7. Spindle sarcoma of the breast.—A married woman fifty-six years of age, with ten children, was admitted into the Cancer Hospital, Brompton, on Nov. 29th, 1886. A hard,

solid tumour the size of a hen's egg was deeply situated in the right breast; there was no glandular enlargement. The patient stated that the duration was five weeks; she had done much hard work, lifting weights, &c. On removal the growth was microscopically shown to be a spindle-sarcoma; the axilla was untouched. No recurrence had taken place up to December, 1893.

CASE 8. Cystic spindle-sarcoma of the breast.—A married woman fifty years of age, with eight children, was admitted to the Cancer Hospital, Brompton, on May 31st, 1886. The patient had a tumour as large as a walnut at the root of the right nipple; this retracted, and there was induration around it; occasional lancinating pain with sensation of heat was experienced; there were no enlarged glands. On removal it was found to be a cyst containing dark-brown fluid with cholesterol crystals; part of the wall was extremely hard and nodular; under the microscope it consisted of embryonic spindle-celled tissue (sarcoma). The patient was well and without further trouble when seen on Dec. 22nd, 1893.

Space permits no more than a passing reference to the less prevalent cancer-species. Of one, however, Melanotic cancer of the skin, it is necessary to remark that, this being now shown to be a product of the Malpighian pigmented epithelium, "anticipatory" removal of the neighbouring lymph glands is demanded exactly as in ordinary epithelioma. We have next to consider that local malady which is most answerable for the quotation cited in the opening sentence, and which for generations has most strongly coloured the universal conceptions of "cancer." Carcinoma of the mamma furnishes all those obstacles to surgical eradication which we meet with in carcinomatous or analogous lesions elsewhere, with one of very grave significance peculiar to itself—viz., *insidious marrow infection*. The disease invariably begins in a minute tissue area, in a single acinus—it may be, in a single cell—following always the operation of some definite exciting cause. In 11.5 per cent. this is mechanical violence; a blow often serves to indicate the precise date of inception. In the remaining 88.5 per cent. mental trouble is the most potent excitant, producing aberrations in the normal devolution of the organ, carcinoma being only one of several lesions due to interference with this process. The mamma undergoes *evolution* between the ages of fourteen and twenty-five; for the next ten years temporary *involution* ensues upon pregnancy, a process of development followed by a resting stage, which is copied in slighter degree by the phenomena of each menstrual period.³ The *devolution* or stage of permanent degeneracy commences about the age of thirty-five, and is the epoch affected by carcinoma almost exclusively. Infection of the lymph glands in the adjacent axilla by the last-named takes place early; it is rarely delayed beyond eight weeks, occasional exceptions being presented by—(1) scirrhus growths within the dense fibrous structures of the nipple, which are exceptionally chronic; (2) "atrophic" cases in withered mamma; (3) carcinomata at the sternal border, which tend first to infect the thymus by lymphatics perforating the chest wall. When enlargement of the axillary glands takes place the normal lymph-current is unable to pursue its ordinary course, and regurgitation takes place in abnormal directions. Thus particles pass, on the one hand, into the marrow of the adjoining humerus (normally this bone is the earliest affected in the majority of instances), and, on the other hand, into the residual thymus, thus producing the condition denominated the "sternal symptom," a progressive prominence of that bone between the second costo-sternal articulations, the most unmistakable evidence of marrow deposit. Implication of the marrow takes place simultaneously with palpable enlargement of the axillary glands, which, as has been pointed out, is a relatively late stage of cell growth therein. Its occurrence must therefore be assumed in every average case of more than eight to twelve weeks' duration, those "atrophic" growths which permit life for from twenty to thirty years constituting an exception. Marrow infection has been shown to occur in at least eight out of every ten instances of mammary scirrhus; it necessarily leads eventually to the passage of cell-particles into the circulation, with metastases in the viscera. After excision of the mamma at a later period than eight to twelve weeks the symptoms become manifest after a variable period of years, rarely exceeding five. In order to surgically eradicate

³ See remarks on this point in the Proclivity of Women to Cancer.

a carcinomatous breast, therefore, an operation must take place within six to twelve weeks of inception, prior to lymph gland enlargement, and before the possible advent of marrow infection. And not only must the tissues be very freely removed, with careful consideration of the exigencies in each individual case, but the axilla at the same time carefully cleared before the lymph glands have had time to enlarge. The old-fashioned text-book operation by two oval incisions passing close to the palpable lesion is necessarily followed by "recurrence" in the cicatrix within a few weeks or months at the outside; the modern methods of procedure rarely fail to secure absence of visible deposit for at least two years, even in what must be considered advanced cases of more than a twelvemonth's duration, complete success being then precluded by the previously established marrow condition. The following instances exemplify the conditions both of success and of relative failure.

CASE 9. *Breast scirrhus excised in February 1887; no recurrence.*—A married woman forty-two years of age, with four children, had a hard "lump" above the right nipple in the breast tissue; the duration was stated to be five weeks. There were intermittent burning sensations; in the axilla tenderness was felt on pressure, but no enlargement; no marrow symptoms were present. Operation was advised on Dec. 20th, 1886, but the patient refused until Feb. 27th, 1887. Free removal of the breast parenchyma, together with the contents of the axilla, was performed; under the microscope the growth exhibited the ordinary phenomena of early carcinoma. The patient has had no reappearance; she was last heard of in good health and with no marrow symptoms in December, 1893.

CASE 10. *Scirrhus excised in May, 1880; no recurrence.*—A married woman fifty-six years of age, with no children, was admitted into the Cancer Hospital, Brompton, on May 21st, 1880. A hard scirrhous "kernel" as large as a walnut was present in the sternal half of the right breast. She stated the duration to be two months. A gland in the axilla was slightly enlarged. There was occasional lancinating pain; no marrow symptoms existed. Excision was performed, with careful dissection of a wide margin of the seemingly healthy tissue around the breast tumour and evacuation of the axilla. The disease on section proved to be a typical carcinoma. The patient came again on July 11th, 1892, for a small ulcer on the gums; there had been no recurrence of cancer in any shape.

CASE 11. *Breast scirrhus excised in October, 1885; two recurrences; subsequent immunity.*—A married woman aged forty-five years, with one child, was admitted to the Cancer Hospital, Brompton, on Oct. 18th, 1885, with nodulated tumour ("hazel nut") deeply situated in a gland tissue at the upper part of the right breast; a gland as large as a horse-bean in the corresponding axilla. She stated the duration to be one year. On removal the microscope revealed a typical acinar carcinoma-structure, with the remarkable and probably unique addition of abundant myeloid corpuscles. In February, 1887, the patient was readmitted to hospital for the excision of a recurrent nodule at the inner end of the scar, with another gland in the axilla. Again, in October of the same year, two deposits as large as beans were dissected out of the pectoralis fibres. All these latter presented the same curious microscopic features as the primary lesion. The patient experienced no further trouble, and was last seen on May 21st, 1894, in good health and without any trace of cancer. From the previous rapidity of the reappearances and the long subsequent immunity, the permanence of the latter may reasonably be inferred.

CASE 12. *Encephaloid carcinoma of the breast; immunity for four and a half years; death from another cause, with no trace of disease at necropsy.*—A married woman aged fifty-two years, with fifteen children, was seen on Feb. 22nd, 1886. The left nipple was retracted. At its root there was a movable tumour, rapidly growing, the size of a small orange, of stated duration seven months. There was slight enlargement of the axillary glands. On removal the appearances were as above. Death took place in August, 1890, and was ascribed to gall-stones. A necropsy was made (in the provinces) by two medical practitioners, who "could detect no trace of cancer." In this and the case following, which were not personally observed until their termination, it is not, however, possible to be certain that marrow deposit was absent.

CASE 13. *Breast scirrhus excised in July, 1888; death from tubercle in 1891.*—A married woman fifty-three years of age, with six children, had to the inner side of the left breast a movable solid tumour ("walnut"); a gland the size of a

bean was in the axilla. There was continuous aching with occasional lancinating pain; she stated that its duration was ten weeks and consecutive to a blow at that period. After excision it proved to be a typical scirrhus. The patient was discharged well on Aug. 24th, and has not been seen subsequently. According to her relatives she died on Feb. 14th, 1891, from "rapid consumption, as shown by the doctor's certificate; she had no symptom whatever of the return of the cancer."

CASE 14. *Breast carcinoma excised; symptoms of marrow infection delayed until ten years afterwards; good health with no palpable cancer deposit fifteen years and a half after operation.*—A married woman fifty-one years of age was admitted into the Cancer Hospital, Brompton, on Oct. 17th, 1879. At the outer aspect of the left breast there was a hard, movable scirrhus as big as an orange, and in the axilla a gland the size of a large bean. She stated the duration to be six months, and attributed it to ill-usage by her drunken husband. After excision of the breast and axillary contents no complaint was made of any bad symptom until February, 1889. Then the lumbar and scapular gnawing "rheumatic" pains pointing to marrow deposit were first mentioned; no deposit in any other tissue was to be found on close examination. The patient (from a distant provincial town) was not seen again until Aug. 3rd, 1891, when a new scar was visible near the axillary end of the old one; and she stated that a "lump" had been removed at the local infirmary a year previously. The note in my out-patient book at this date runs: "Cicatrix healthy; no tumour or gland enlargement anywhere. The 'sternal prominence' very conspicuous; aching pains down left arm, through left scapula, and across front of chest; tenderness on pressure at two points on left scapula just above angle." The patient attended again on Jan. 7th, 1895. She is a florid, robust-looking woman, with a marked protuberance of almost the entire sternum, and complained of aching soreness in that region, but otherwise she was free from any trace of cancerous disease. The long delay in appearance of marrow symptoms here is unprecedented in my experience. The two cases following exhibit the average rule.

CASE 15. *Excision of breast scirrhus; marrow infection not apparent till five years subsequently, followed by nodular deposits.*—A married woman forty years of age, with six children, was admitted into the Cancer Hospital, Brompton, on June 13th, 1887. To the outer side of the left nipple there was a hard scirrhous kernel the size of a walnut and freely movable, and in the axilla a gland as large as a bean. The stated duration was three months, but the real duration, as inferred from the physical condition, was probably from six to twelve months. No marrow symptoms were present. After the usual operation nothing wrong was observed until Dec. 2nd, 1892; then the "sternal symptom" made its appearance, and slowly increased to the ordinary stationary point. A year later (Dec. 4th, 1893) two nodules, each as large as a pin's head, were detected close to the sternum, rather deeply situated in the second intercostal space. On Jan. 1st, 1894, a third minute speck was found in the middle line, with a lymph gland as large as a hazel nut in the right axilla. Excision of all these was performed, and the patient was discharged well. The scar left by operation on the left breast and axilla has remained throughout perfectly sound, and the general health is fairly good. (Now, Jan. 1895, the patient is breaking down.)

CASE 16. *Removal of advanced breast carcinoma; no recurrence in situ, but death seven years subsequently from bone lesions.*—A married woman sixty-one years of age, with six children, was admitted to hospital in July, 1886, for very hard, round scirrhus an inch and a half in diameter at the upper part of the right breast. The stated duration was three months; the real duration was evidently much longer, apparently one or two years.⁴ The disease was of specially chronic appearance; the glands were tender, but not appreciably enlarged; there were no marrow phenomena. The patient was a thin, worn, woman with a disorganised eyeball, which was simultaneously removed with the breast and axillary contents. She was in good health in March and November, 1889, but was then lost sight of until June 19th, 1893, when she reappeared with a cluster of diseased glands in the left axilla, the right remaining perfectly free and the cicatrix healthy. There was a small, livid nodule under the skin covering the xiphoid cartilage.

⁴ Women almost invariably understate the period, the margin of conscious suppression varying from six weeks to two years.

The most noteworthy physical sign was afforded by the sternum, which constituted almost a tumour, the whole bone projecting prominently forwards and being greatly thickened. In July paraplegia supervened, signifying deposit within the vertebrae, and death took place in September, 1893.⁵

CASE 17. *Excision of advanced breast scirrhus; marrow symptoms three years later; no palpable recurrence four years after operation.*—A woman fifty-four years of age had the left breast excised for a chronic scirrhus tumour, of at least eighteen months' duration, in January, 1881, with enlarged glands in the axilla. The health remained good till March 14th, 1884; then first appeared the "sternal prominence," with some dyspnoea and dry cough. In February, 1885, deposit was also found in both axillae, but the patient was still able to do her work as a domestic servant. The scar left by the breast amputation was healthy. There was no subsequent attendance.

CASE 18. *Excision of advanced mammary carcinoma; marrow infection after two years; spontaneous fracture of sternum and tumour formation.*—A married woman fifty-two years of age had the left breast &c. excised in August, 1886. A mass of encephaloid carcinoma as large as an orange occupied the whole area; its stated duration was six months, but a blow one year previously more accurately fixed the inception. The glands were necessarily implicated. No note was made of the marrow condition, the routine occurrence of marrow infection in these cases not having been discovered until 1890. The patient was in good health subsequently until November, 1887; then, after turning in bed, she felt a sudden snap at the upper part of the sternum; she again attended the hospital as an out-patient, when marked thickening of the bone was the only lesion found. On July 23rd, 1888, a livid prominent boss as large as a child's head protruded from the spot indicated. The scar was healthy; there was no sign of axillary or of visceral deposit.⁶

CASE 19. *Ulcerated breast scirrhus of long standing; excision in March, 1892; immunity save for marrow infection to present time.*—A widow sixty-four years of age, stout, applied in August, 1888, with a cyst of twenty years' duration at the root of the left nipple. For the previous eighteen months there had been induration around this and lancinating pain (denoting carcinoma development). Operation was urged, but was declined till four years later (August, 1892); then the nipple was eroded (in its place being a scirrhus ulcer one inch in diameter), there was deep infiltration of the gland tissue at its base, together with deposit in the axilla. The "sternal prominence," as usual in stout patients, was well marked. There has been no recurrence to the present time (Jan., 1895); the woman is in good health and unconscious of any ailment.

CASE 20. *Advanced encephaloid carcinoma excised three years; no recurrence to present date.*—A married woman forty-three years of age, very stout, with large mammae, had in the right breast a movable roundish mass the size of a pigeon's egg; it had been noticed for six months. There were also slight gland enlargement and intermittent darting pain, but no marrow symptoms. Excision was performed in October, 1891, when it was found to be a soft grey carcinoma; there were deposits in several axillary glands, the largest as big as a damson; their size had previously been obscured by the abundant fat. The patient still attends every two months as out-patient, but is without visible disease and is in excellent general health.

CASE 21. *Advanced scirrhus excised two years; no recurrence to present time, but progressive marrow infection.*—A widow sixty-five years of age, with one child, when seen had in the left breast induration and retraction of the nipple, which had been noticed for eight months; probably they were of much longer duration. Slight enlargement and tenderness of the axillary glands were present; the "sternal prominence" was very marked. An operation was performed in November, 1890. To present date the scar is healthy, and there is no trace of recurrent deposit other than of that in the marrow. The patient now begins to complain of severe aching, with sensation of pressure at the spot in question on the sternum; she also complains of rheumatic pains in both scapulae, down the left arm, &c.

⁵ Photographs of the sternum in this and in the case preceding were exhibited at the Nottingham meeting of the British Medical Association in 1892.

⁶ The "sternal prominence" proceeds to actual tumour development in not more than 2 per cent. of the total cases. For original description of these insidious marrow lesions, and their recognition as of routine occurrence, see THE LANCET, March 7th and 14th, 1891; Brit. Med. Jour., vol. i. 1892.

Note.—Continuous opium treatment commencing immediately after convalescence is strictly enjoined upon all my breast-excision cases in which any suspicion of antecedent marrow infection exists, and accounts for the prolonged immunity of some of the preceding cases. It is often, however, difficult to ensure in hospital patients living at considerable distances.

THE ABSENCE OF SUGAR FROM NORMAL URINE PROVED BY A NEW AND SIMPLE METHOD.

By SIR GEORGE JOHNSON, M.D., F.R.S.,

EMERITUS PROFESSOR OF CLINICAL MEDICINE AND CONSULTING PHYSICIAN TO KING'S COLLEGE HOSPITAL; PHYSICIAN EXTRAORDINARY TO HER MAJESTY THE QUEEN.

WHETHER a trace of sugar exists in normal urine is a question of interest to chemists and physiologists, but one of no practical importance. For the clinical observer the presence or absence of glycosuria may be decided in about two minutes by the following simple test. A drachm of urine—or, what is nearly the same amount, 4 c.c.—is placed in a test tube about half an inch in diameter, and to this is added an equal volume of a saturated aqueous solution of picric acid, and half the volume—that is, half a drachm, or 2 c.c.—of liquor potassæ (P.B.).¹ An orange-red colour instantly appears as a result of the incipient reducing action of kreatinine upon picric acid at the ordinary temperature. The colour is deepened by boiling, and if after the liquid has been kept at the boiling point for about a minute a bright red colour appears through the test-tube when held up to the light, the urine for clinical purposes, may be confidently pronounced free from sugar. If an aqueous solution of glucose, in the proportion of not more than two grains to the ounce, be tested in the manner described, the liquid will be rendered so dark that no light is visible through the full diameter of the tube. I confidently assert that, for clinical and life assurance purposes, no other method of testing for glycosuria equals this for the ease and rapidity with which it may be conducted and for the absolute trustworthiness of the result. The presence of sugar having been thus ascertained, the quantitative determination may be speedily and accurately effected by means of the picrosaccharometer. The method of using the saccharometer is described in an appendix to this communication. Since the publication of my paper on Some Common Sources of Error in Testing for Sugar in the Urine,² and the correspondence to which it gave rise, I have obtained additional, and I believe conclusive, evidence that no trace of sugar is to be found in normal urine. The nature of this evidence I now propose to submit to the readers of THE LANCET. It will be remembered that in the paper referred to I attached great importance to my son George Stillingfleet Johnson's discovery that by the action of mercuric chloride the kreatinine, which is a constant constituent of the urine, is precipitated, in combination with mercury, as a definite chemical compound, from which, the kreatinine having been separated in a crystalline form, its ultimate composition and its reducing action upon cupric oxide and picric acid have been accurately determined.³ The kreatinine having thus been separated from the urine, it is found that the filtrate exerts no reducing action upon either the copper or the picric acid test. In other words, there is found no trace of sugar. The picric acid test would detect one-hundredth part. of glucose if so small an amount were present, and that any sugar which might be present is not removed by the mercuric chloride process is proved by the fact that when a known weight of glucose is added to the urine it is found undiminished after the separation of the kreatinine. That by avoiding the application of heat and destructive chemical agents my son has succeeded in separating unchanged the natural kreatinine of the urine, and that this is the sole agent in normal urine which exerts a reducing action

¹ See a letter by the writer on the Value of Picric Acid as a Test, in THE LANCET of Jan. 23rd, 1894.

² THE LANCET, July 7th, 1894.

³ The details of this investigation are published in the forty-third volume of the Proceedings of the Royal Society, and more briefly in the sixty-third volume of the Transactions of the Royal Medical and Chirurgical Society.

upon picric acid,⁴ is proved by the fact that when the amount of picric acid reduction by urine has been accurately determined the corresponding indicated amount of Stillingfleet Johnson's kreatinine in aqueous solution is found to give precisely the same degree of picric acid reduction colour as the urine, when the liquids are undiluted, and in different stages of dilution until the amount of kreatinine is no more than one grain by weight in 200,000 minims of liquid, the comparison being made with a pale yellow solution of picrate of potash. To obtain the complete reduction of picric acid by an aqueous solution of kreatinine containing about a grain to the ounce, more potash is required than in testing normal urine. The amount of liquor potassæ (P.B.) must be one and a half drachms instead of half a drachm, and the liquid should be boiled for ninety seconds. The kreatinine in the urine appears to be associated with some substance which enables it to exert its full reducing action in the presence of a smaller amount of potash than is necessary when uncombined kreatinine is dissolved in water. In testing largely diluted solutions of kreatinine the usual half-drachm of liquor potassæ is sufficient. For comparing the colours resulting from testing diluted urine and an equally diluted solution of kreatinine the simplest plan is to place a drachm of each liquid in two test-tubes of equal diameter, to add to each a drachm of picric acid solution and half a drachm of liquor potassæ, then to boil for a minute, after which, the two tubes being placed side by side, the equality or the difference of colour can be observed. If, as has been asserted, glucose were present in normal urine in the proportion of not less than 0.05 per cent., about one-third of the reducing action upon picric acid would be caused by glucose, and the remaining two-thirds by kreatinine. Now, the extreme delicacy of the picric acid reaction with kreatinine in largely diluted solutions affords a simple and accurate means of detecting a mixture of a small quantity of glucose with kreatinine, whether in the urine or in an aqueous solution. I have ascertained by repeated experiments that a watery solution of glucose ceases to give any colouration with picric acid and potash when the dilution is carried beyond 1 part in 10,000 of liquid. If, therefore, the reduction colour in normal urine were in part due to the presence of a small proportion of glucose, the colour resulting from the analysis of the urine and of an aqueous solution of kreatinine of the same reducing power, which is equal when the two liquids are undiluted, would be unequal when the dilution is carried beyond the point—that is, one grain in 10,000 minims of liquid—at which glucose ceases to exert any reducing action upon picric acid. The urine would be paler than the equally diluted solution of kreatinine in proportion to the amount of sugar which it contains.

I have tested many specimens of normal urine by comparing the colour resulting from the picric acid test with a solution of kreatinine of equal reducing power, and I have invariably found that when the colours in the undiluted specimens have been equal they have remained equal after the two liquids have been diluted beyond the point at which the action of glucose must have been eliminated. It has occasionally happened that the reduction colour of the urine has been slightly under-estimated, and the kreatinine solution has consequently given a somewhat paler colour. In these cases the darker colour of the urine has been visible through every stage of dilution of the two tested liquids. The conclusion is that kreatinine is the only substance in normal urine that exerts a reducing action upon picric acid, and that not a trace of glucose is present.

The assumption that since sugar exists in the blood it must be found in normal urine ignores the fact that sugar, like albumen, is a nutrient material, the separation of either of which by the kidneys is wasteful, while, on the contrary, all the solid constituents of normal urine are excrementitious and their retention in the blood is injurious. The copious excretion of sugar in cases of diabetes is often associated with albuminuria, and in the advanced stages with structural changes in the kidneys. The sugar not being a normal constituent of the urine, its continual passage in large quantities through the kidneys injuriously affects their structure and functions, the result in some cases being a more or less complete suppression of urine. The conclusion derived from the experiments before described, that normal urine contains no sugar, is confirmed by the contrasted results obtained when a small but known quantity of

sugar has been added to the urine. The following experiment is typical of many others that I have performed, with essentially identical results. A sample of urine (sp. gr. 1015) gave with picric acid a depth of colour indicating 0.6 grain per ounce calculated as glucose. To an ounce of this was added 0.3 grain of glucose. By this addition the amount of reduction was of course raised to 0.9 grain per ounce, two-thirds being due to kreatinine and one-third to glucose. The reducing power of kreatinine being less than that of glucose in the proportion of 10 to 12, the amount of kreatinine required to give the same colour as this saccharine urine was 1.08 grain in an ounce of water. The testing of the undiluted urine and the kreatinine solution respectively gave a red colouration of exactly the same tint. When the two liquids were tested after being ten times diluted the diminished reducing action of the glucose was shown by the fact that the colour of the urine was slightly paler than that of the kreatinine solution. The difference was more marked in the twenty times diluted liquids, and it was still more conspicuous when, the dilution having been increased to thirty, the proportion of the reducing material in the liquid was only 1 in 14,400, and the action of glucose was thus entirely eliminated. If it had not been known that one-third of the reducing action of the undiluted urine was caused by the added glucose, the fact might have been ascertained by observing that in order to equalise the colour of the two liquids when tested after dilution had been carried beyond the point at which glucose ceased to exert its reducing influence, one-third of its volume of water had to be added to the kreatinine solution. Here, then, we have a simple method by which not only the absence of sugar from normal urine may be ascertained, but the exceptional presence of a small amount may be quantitatively determined, such exceptional presence being, I believe, very rare indeed.

The following experiment I have repeatedly performed with the same invariable result. A sample of urine gave with the picric acid test a reduction colour indicating 0.8 gr. per ounce, calculated as glucose. A solution of kreatinine, in the proportion of 0.96 of a grain to the ounce, gave the same reduction colour. To an ounce of the urine was added a quarter of a grain of glucose, by which the reduction was increased to 1.05. The saccharine urine, after being diluted thirty times and tested, gave exactly the same colour as the solution of kreatinine and the same as the urine before the addition of glucose on being equally diluted. The reducing action of the glucose was eliminated by the dilution, while that of the kreatinine in the urine and in the aqueous solution still afforded an equal shade of colour. It will be seen that, while the result of these experiments confirms my son's statement that after the removal of kreatinine from normal urine by mercuric chloride the filtrate contains no trace of sugar, the evidence which I have obtained is of an entirely different and independent character. My experiments, however, are so far an outcome of his laborious and accurate investigations that I could not have performed them if he had not supplied me with the pure unchanged urinary kreatinine. The mercuric chloride and the picric acid process, by which the absence of sugar is proved, are free from the source of fallacy which is common to all the methods by which the presence of sugar has been supposed to be shown—namely, that of mistaking the product of chemical operations upon the constituents of the urine for a true pre-existing educt.

It is probable that many members of the medical and chemical professions will repeat the experiments which I have here described. For this purpose they will have to obtain the pure urinary kreatinine, which has hitherto been a difficulty. My son tells me that no specimen of kreatinine which he has purchased has been pure, and I have lately obtained from a German firm a sample labeled and charged as kreatinine which contained a mere trace of that substance, while the bulk of it had all the distinctive characters of kreatine. I have authority for stating that the pure urinary kreatinine will shortly be for sale at the Apothecaries' Hall, the society having made arrangements for its preparation by the process which my son has successfully initiated and described in the two papers before mentioned, one of the main points being that the crystallised kreatinine is obtained by evaporation *in vacuo*, since a boiling temperature alters its characters and often converts it more or less completely into kreatine by the addition of a molecule of water.

I have lately met with an exceptional specimen of

⁴ Uric acid reduces cupric oxide, but not picric acid.

non-saccharine urine of specific gravity 1039. The urine was turbid with urates, cleared by heat, and contained no albumen; with nitric acid in excess the urine became nearly solid with crystals of nitrate of urea. The picric acid reduction was 1·8 gr., calculated as glucose, indicating 1·9 gr. of kreatinine per fluid ounce. The urine and the solution of kreatinine being diluted successively from ten to forty times gave with the picric acid test an equal shade of colour, or if there was any difference the urine was very slightly darker than the kreatinine solution at each successive stage of dilution. Only by this method of testing or by precipitating the kreatinine by the mercuric chloride process could this urine of high specific gravity, containing an excess of normal constituents, have been confidently pronounced to be free from sugar. The amount of kreatinine in this specimen is larger than in any urine that I have hitherto analysed. The average reduction with picric acid in normal urine is about 0·8 per ounce calculated as glucose, indicating practically a grain of kreatinine in each fluid ounce of urine.

Dr. Pavy in his work on "The Physiology of the Carbohydrates" (pp. 186-7) estimates the amount of sugar in normal urine to be "about 0·5 or a little over per 1000," but this estimate is arrived at by assuming that after the removal of uric acid the cupric oxide reduction found to occur is produced entirely by sugar. It will be seen, then, that Dr. Pavy entirely ignores the existence and the reducing action of kreatinine, and it is not a little remarkable that throughout the work in question there is no mention of the two almost ubiquitous cupric oxide reducing agents kreatine and kreatinine. It is certain that a portion at least of the reducing action of various tissues and liquids which Dr. Pavy attributes entirely to sugar is due to one or both of these organic bodies, yet there is no indication throughout his book that, being aware of this source of error in estimating the amount of sugar, he has been careful to guard against it.

It is interesting and practically useful to note that while glucose, kreatine, and kreatinine alike, though in slightly different degrees, reduce cupric oxide and picric acid, when boiled with an alkali there is a significant difference in the action of each upon picric acid at the ordinary temperature. Thus when picric acid and potash are added to a cold solution of kreatinine or to normal urine, of which that substance is a constant constituent, an orange-red colouration, the result of incipient reduction of picric acid, occurs immediately; with kreatine at least an hour elapses before any red colouration occurs, and with glucose there is an interval of at least six hours before any change of colour appears at the ordinary temperature. With each of the three substances the colour is gradually deepened in the course of from twelve to twenty-four hours, but in none of them is the reduction of the yellow picric to the red picramic acid complete until the liquid has been boiled for about a minute. With regard to the loss of reducing action upon picric acid by dilution kreatine is intermediate between glucose and kreatinine. The limit is one grain to about 50,000 mm. of water, being five times more than the limit of glucose, and four times less than that of kreatinine. The difference between kreatine and kreatinine as regards their reducing power in dilute solutions affords a means for the detection of a mixture of the two substances; while another mode of detecting the mixture, such as is found in Liebig's and other meat extracts, consists in precipitating the kreatinine by mercuric chloride, when the kreatine is left in the filtrate and may be detected by the picric acid reaction commencing in from an hour to an hour and a half at the ordinary temperature. It will be seen that the three substances kreatinine, kreatine, and glucose stand to each other in the same relation as regards the time required to develop the incipient picric acid reaction at the ordinary temperature, and also as regards the limit of dilution beyond which no reaction occurs even at the boiling temperature. In both these respects kreatine occupies a position intermediate between kreatinine and glucose, but in its reducing power upon picric acid at the boiling temperature kreatine is at the bottom of the list, being inferior to kreatinine in the proportion of about six to seven.

In conclusion, I may mention a simple test by which crystals of kreatine may be distinguished from those of kreatinine. The former, when placed in a test tube and heated for a few minutes in a water bath, lose water and become opaque, while the latter remain transparent. This easily applied test will enable a purchaser to ascertain whether the material which is sold as kreatinine is what it is declared to be. An aqueous solution of kreatinine gives with

picric acid and potash at the ordinary temperature an instantaneous red colouration; a solution of kreatine gives, when cold, no red colour for at least an hour.

APPENDIX.

DIRECTIONS FOR THE QUANTITATIVE ESTIMATION OF SUGAR IN URINE BY SIR GEORGE JOHNSON'S PICO-SACCHAROMETER. MADE BY MESSRS. C. E. MÜLLER & Co., 148, HIGH HOLBORN, W.C.

The following solutions are required:—

1. Standard solution of ferric acetate, equal in tint to that yielded by a solution of glucose containing 1 grain per fl. oz. This standard solution is prepared as follows:—

℞ Liquor ferri perchloridi fortior (P.B., sp. gr. 1·42) 3j.
Acidi acetici glacialis (P.B., sp. gr. 1·058) ... 3iv.
Liquor ammoniac (P.B., sp. gr. 0·959) ... 3ij.
Aquam destillatam ... ad 5iv.

Mix first the iron and the acid; then add the ammonia, and water up to 4 fl. oz.⁵

2. Saturated solution of picric acid, prepared by boiling the crystals with distilled water in the proportion of 6 grains to 1 fl. oz., and allowing the excess to crystallise out on cooling.

3. Liquor potassæ (P.B., sp. gr. 1·058).

Apparatus required.

1. A tube about 12 inches in length, graduated into 100 cubic centimetres, with longer divisions at each 10 cubic centimetres, accurately stoppered and lipped.

2. A tube, half the above length and of equal diameter, accurately stoppered to hold the standard solution.

3. A boiling tube, 10 inches long, $\frac{1}{2}$ inch in diameter (internal), lipped, and graduated up to 4 fl. drachms.

4. One drachm measure.

Method of performing the Analysis.

Measure 1 fl. drachm of urine into the boiling tube. Add 1 fl. drachm of the saturated picric acid solution, and $\frac{1}{2}$ fl. drachm of liquor potassæ. Make up to the 4 drachm mark on the tube with distilled or rain water. Heat over a spirit or gas lamp, and keep the liquid boiling for about a minute. Cool by dipping the tube after a minute in cold water, and ascertain that the cold liquid measures exactly 4 fl. drachms. If less, make up to the 4 drachm mark with distilled water; if more, evaporate down to the 4 drachm mark. If the colour of the boiled liquid is the same as that of the ferric acetate standard or paler, the urine is either free from sugar or contains less than 1 grain per fl. oz. If the colour is paler than the standard, boil with 2 drachms of urine instead of 1, then divide the indicated reduction by 2. In analysing an undiluted urine the phosphates precipitated by the potash often cause turbidity, which must be removed by filtration before the colour can be accurately estimated. It should be borne in mind that all normal urines reduce picric acid to an extent equivalent to from $\frac{1}{2}$ grain to 1·2 grain of glucose per fl. oz. This reduction is due to kreatinine. This should be allowed for when the quantity of glucose present is very small. If the colour of the boiled liquid is darker than the standard, introduce it into the graduated tube until it stands at 10 divisions, whilst the stoppered tube at the side is filled with the ferric acetate standard. Now dilute the dark-red liquid in the graduated tube with distilled or rain water till the colour is the same as that of the standard. Each division above 10 = 0·1 grain per fl. oz. Thus, 13 div. = 1·3 grains, 30 div. = 3 grains per fl. oz., &c. If more than 6 grains per fl. oz. are indicated,⁶ dilute the urine 10 times by pouring urine up to 10 divisions on the graduated tube, and distilled or rain water up to 100. Then analyse the diluted liquid as before. In this case each division on the saccharometer indicates 1 grain of sugar per fl. oz. Thus, diluting from 10 up to 48 divisions shows that the urine contains 48 grains of sugar per fl. oz. If the urine, when 10 times diluted, gives a colour paler than the standard, it contains less than 10 grains of sugar per fl. oz. Another portion should then be diluted 5 times by filling the graduated tube up to 10 divisions with urine, then up to 50 divisions with distilled or rain water.⁷ The analysis is performed as before. The value of the divisions now will be half that with a 10 times

⁵ The ferric acetate standard may be obtained from any pharmaceutical chemist.

⁶ The reason for this is that 1 fl. drachm of picric acid solution is sufficient for the decomposition of not more than that proportion of sugar.

⁷ The dilution of the urine may be more conveniently made by pouring 5 or 10 c.c. into a 50 c.c. flask and adding water up to the 50 c.c. mark.

diluted sample. Thus, 18 divisions would indicate 9 gr. per fl. oz. If the urine has a specific gravity of 1035 or more it should be at once diluted 5 or 10 times before commencing an analysis.

The percentage weight of sugar to the volume of urine may be ascertained by dividing the number of grains per fl. oz. by 4·8 Savile-row, W.

FRACTURE OF THE NECK OF THE FEMUR IN THE EIGHTY-EIGHTH YEAR OF AGE; RECOVERY, WITH BONY UNION.

By W. PUGIN THORNTON, M.R.C.S. ENG.

FOR anybody in the eighty-eighth year, after fracture of the neck of a thigh bone, to recover sufficiently to be able to walk with the aid of crutches warrants, I think, the publication of the case. A retired colonel, aged eighty-seven years on his last birthday, in vigorous health and accustomed to daily unassisted outdoor walking exercise, had driven on the afternoon of April 2nd, 1894, a one-horse four-wheeled carriage two miles in the country. He was standing before the horse, altering the bit, when it suddenly bolted and knocked him over. He was found shortly after the accident sensible but helpless on the ground. After some delay he was brought into the town in a carriage. I saw the patient two hours after the accident, and helped to carry him into his house. He complained of excruciating pain about the right hip on any movements of the leg, which he did not feel when the limb was at rest. This leg was helpless, slightly everted, and apparently without shortening. When moving him from the carriage to his bed he could, when supported, bear weight on the left leg. On sending a message to Messrs. Preston and Prentice, surgeons in this town, these gentlemen arrived in about an hour's time, very acceptably bringing chloroform, splints, &c. We then put the patient under chloroform and, having first emptied the bladder, the urine being clear, examined the right leg. I immediately found crepitus at the neck of the femur. Mr. Preston then examined and then Mr. Prentice, but neither produced the evidence of fracture. We put up the leg in a splint extending from the axilla to some inches beyond the foot. On the following day, at 12 A.M., the patient's temperature was 101½° F. It reached this height once again in April. Three times between April 3rd and June 3rd it was 100½°, otherwise ranging from 100° to 97°. The pulse during these two months usually kept from 80 to 90, and the respiration from 20 to 24, but at times the patient had severe attacks of sighing, which occasionally ended with breathlessness, and hardly an appreciable pulse. These attacks were relieved by brandy and permanently stopped by citrate of caffeine. As he was delirious for the first few nights after the accident it was necessary to have four nurses. Besides being powerful, he was a heavy man, so that two nurses at night time and two during the day for the first three weeks, until he could help somewhat in being turned on to his side, were a necessity. For the first month he was kept on a water-bed, and after that time on an American wire-braided mattress. When on the water-bed a small sore came on his back, but through the assiduous care of his nurses it only lasted a few days. On the fifth day after the accident pain was felt in the left leg, and a bruise was noticed close above the knee to half-way up the thigh, running inwards, and corresponding to the breadth of the tire of a carriage wheel. From that time this leg, especially at the back of the knee, gave the patient more pain than the right; and when he first attempted to walk it was the most painful of the two. On May 14th the long splint was taken off and sandbags were used for a fortnight. He was measured by Mr. Hawesley for a Durham's steel screw splint, so that I might get him sooner out of bed than I could otherwise have done. His right leg at that time was almost entirely free from swelling and could be flexed without pain. He could also, with a little assistance, turn himself in bed and could sit up with the aid of a bed-rest for some hours; but between the time of measuring and sitting on the splint the patient one day, in the absence of the nurse, assisted by a relative, so exercised his leg that the same evening there was

a rise of temperature, a restless night, and soon a thick swelling under the whole length of the ilio-tibial band of the fascia lata. This swelling remained the same for more than a month. It could be broken up by pressure into portions of any size. At the same time the pain at the hip returned, and the leg and foot were as oedematous as they had been after the accident. Accordingly I had to give up all idea of using Durham's splint, and could only continue keeping the patient in bed. At this time the right leg measured in length half an inch less than the left. On Aug. 16th I had him up for the first time, he having been four and a half months in bed. He went out in a bath-chair in the garden on the 29th, and for a three hours' drive in the country on the 31st. At the present time the patient is very well in health, and daily goes into the garden in a bath-chair and sometimes for a carriage drive. He is only able to walk a short distance with the aid of his crutches. I do not expect that he will improve in this respect on account of his age.

Canterbury.

CHLOROBROM IN SEA-SICKNESS.

By WALTER FREDERICK DALE, M.R.C.S. ENG.,
L.R.C.P. LOND.

ON my outward voyage to the Falkland Islands seven years ago, to take medical charge of the employés upon a tract of country there, I had a very bad experience of sea-sickness. I tried in succession a number of drugs which had been mentioned as useful, and found them all equally useless. In course of time the actual outbreak of sickness passed away, but during the whole voyage I was never really well. I was never able to smoke. In THE LANCET¹ I noticed an article on the effects of chlorobrom in sea-sickness by Professor Charteris of Glasgow, and when I left the colony in May last year I took with me a supply of this solution. As recommended, I took a dose of it a couple of nights before going to bed. We left in the early morning, and when we got out into the sea-way a fairly good sea was running, but I was able to stay on deck all day. At night I had some more chlorobrom and was not sick. At most I felt only an occasional slight nausea. The ship was very full, and the captain very kindly gave up to my wife and myself his cabin, which was fitted with two berths—one parallel, and the other at right angles to the long axis of the steamer. I had thus an opportunity by changing berths of converting pitching into rolling by taking the cross berth. On the third night I was just going to sleep in the parallel berth when I was suddenly aroused by a sensation of sea-sickness. The steamer began to pitch most fearfully, and I scuttled out of my berth to a cross sofa, and there I had a "few mighty mean moments." When the steamer gave an unusually deep dip of her stern I experienced a sensation in my abdomen as though all the intestines were drawn forcibly down about the spinal column, and I believe that by gravitation such was the case. My wife then woke up, and, seeing what a sorry case I was in, gave me the cross berth, and at my request handed me the bottle containing chlorobrom, of which I took about a dessert-spoonful. In about half an hour I repeated that dose. The result was that, although we had an awful night, I not only was not sick, but slept for a fair time during the storm. The next morning the wind had gone down, but the sea was still rather heavy. It was suggested to me that champagne was a very good thing at sea. I exhibited it internally and promptly re-exhibited it, and this was the only time that I was sick during the voyage. Moreover, I was able to smoke during the greater part of the time.

Now there are two possible sources of error in judging of the value of chlorobrom in this case. Firstly, while in the Falkland Islands I had a good deal of cutter work in visiting my patients, which might have made me a better sailor. But I doubt that, for I was never able to stop in the cutter's cabin in heavy weather. Secondly, the cross berth might have had something to do with my comparative immunity; but I am disposed to put down a good deal of my comfort to chlorobrom. The steamer that I came home in carried a German medical man, so that I could not give chlorobrom freely to my fellow-passengers; but I gave some to a lady who was ill and to a man who was having a very bad time of

¹ THE LANCET, April 21st, 1894.

it, and in each case it did good. If ever I go to sea again I shall certainly lay in a stock of chlorobrom. I quite believe, too, in the liver being acted upon before going on board and in cases where the cooking is likely to be bad. I am sure a stock of "comforts," which can be had nowadays in many attractive forms, is a wise investment. Further, I should say where a cross berth does not exist, one might be improvised with a bed-stand chair or a hammock, for I am sure it is the pitching that does the mischief. In support of this it just occurs to me that when I was on board a whaling ship the year before last in the Falkland Islands I asked the captain about the crew's-nest, and he said that when he was up there he did not mind the rolling; but as soon as the ship began to pitch he got sick and had to come down.

There are different views about the causation of sea-sickness; but, in my opinion, it begins in the brain. I noticed a rather curious thing when I was at the Falkland Islands that might, I thought at the time, have some slight bearing upon the view that sea-sickness was due to movement of the cerebro-spinal fluid. The great bulk of my journeys was done on horseback, and in consequence of the roughness of the ground the horse's paces were so irregular that "posting" in the saddle was impossible. We therefore rode military fashion—i.e., sat down and allowed the horse to pitch us up and down in the saddle by his movements. Horses were "rough" or "easy," according to the height of their lift, and there was a vast difference in the fatigue of riding them. But I have noticed repeatedly after riding a long journey (say, thirty miles) on a rough horse (when I had been sitting in my chair for about half an hour) a curious sensation as though somebody had put a hand against the back of my head and suddenly pushed it forwards, and it was always accompanied by a sickening sensation. It only lasted about a second or so, and I might get it twice in the course of the first half hour after getting off horseback, and then no more till after the next long journey on a rough horse. I believe—though, of course, I cannot prove it—that it was caused by cerebro-spinal fluid, which had been drawn down in excess of the normal into the spinal canal by the succussions in the saddle, suddenly escaping back into the fourth ventricle. I think the fact of chlorobrom influencing sea-sickness is a pretty good proof that the latter starts in the brain.

Welling, Kent.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

ANURIA IN THE COURSE OF MALIGNANT UTERINE DISEASE.

By J. J. STACK, L.R.C.P. EDIN., L.R.C.S. IREL.

A WOMAN aged sixty-eight years, a widow, consulted me in November, 1893, complaining of uterine hæmorrhage, a sense of weight and "bearing down" feeling, together with being generally "out of sorts." She had previously been under the treatment of a medical man in her neighbourhood, and had also been operated upon for cataract by Mr. Nettleship. On examination per vaginam there was found to be some slight tenderness and bleeding; the cervix was quite hard, and the womb immovable. There was some erosion round the os uteri. There was no perceptible abdominal swelling, but I thought I felt some abnormal hardness and enlargement of the ovaries. My diagnosis was that of carcinoma, but to what extent the tissues were involved I was unable to say positively; the patient being very nervous and irritable, I was restrained from pursuing my examination to the extent that I should wish. Her past history was that of a dyspeptic, and her chief complaint was constipation and piles. She suffered a good deal during her child-bearing days, and was worried also by financial mishaps. I could get no history of cancer in any of her family. Considering all the circumstances, I advised palliative treatment, believing that surgical interference was out of the question. The bleeding ceased after a hypodermic injection of $\frac{1}{16}$ gr. of ergotinine. I ordered vaginal injections of a warm solution of boric acid with a little cherry-laurel water. These were

continued to the last; and under the circumstances she seemed to get on comparatively well, suffering no pain whatever but an occasional bearing down, which nearly always ceased when some slight hæmorrhage took place. She went to the country on a visit in the early part of September, 1894, and returned on the following month. During her visit she suffered from constipation, and an attack of jaundice supervened, which she attributed to the rich food of which she had been partaking. I again saw her on her return to town. She was then jaundiced and seemed to be very weak. She complained of passing very little water, and owing to her anxiety on that point I gave her two powders of symphoric, in conjunction with other diuretics, without any appreciable effect. Very little water, about a dessert-spoonful, passed for two days; then the kidneys refused to act altogether from Nov. 21st to 29th. I introduced male and female catheters frequently without any result, and am confident that the bladder was quite empty. She took powders containing compound powder of jalap and compound powder of elaterium, and also had half a grain of pilocarpine by the mouth. The latter produced violent diaphoresis, and the combination, I believe, averted uræmia, and distinct improvement followed their administration, though she felt very weak and depressed. I had a medical man's assistance on the 27th, who prognosed immediate death. She was taking champagne and brandy as stimulants. On Nov. 29th copious urination took place—a very cataclysm—and with it the patient's condition was completely changed from a semi-comatose state to that of great excitement, irritability, and want of sleep. She remained quite conscious for a few days, after which she lingered on till Dec. 7th. The jaundice, I believe, marked the incidence of metastasis. Her liver was much enlarged when she returned from the country. But what was the cause of the suppression of urine? Was it due to the presence of bile in the blood? The kidneys seemed to be quite normal, being free from sugar and albumen. There was no post-mortem examination. I cannot recall a similar case, either from observation or from medical authorities.

New-cross, S.E.

TWO CASES OF PHENACETIN RASH.

By R. MILBOURNE WEST, L.R.C.P. LOND.

As there still seems some uncertainty about the existence of a "phenacetin rash," the following two cases may help to clear up the doubt.

Case 1.—A man aged twenty-eight years was taken with slight rigor, violent headache of a neuralgic character, and a feeling of nausea. As the headache formed the most prominent and painful symptom two five-grain phenacetin tablets were administered. Three hours later I again saw the patient, who expressed himself as feeling better; his face, chest, and arms were, however, covered by a dense scarlatiniform rash, slightly raised from the skin surface, and causing a tingling, smarting sensation, as though, to use the patient's own words, he had "been exposed to a violent storm of sleet." Two hours after the onset of the rash it had disappeared, and next morning he was well. On several subsequent occasions I have administered phenacetin to him in doses varying from five to fifteen grains, and on each occasion the same rash, more or less pronounced, according to the dose, has made its appearance.

Case 2.—A young woman, subject to attacks of facial neuralgia, was in the habit of taking phenacetin for their relief in doses varying from five to fifteen grains. On each occasion, from between one to two hours after administration of the drug, an urticarial rash, presenting raised wheals, chiefly on the face and neck, and accompanied by a sensation of heat and tingling, appeared, lasting usually a couple of hours. In neither of the above cases were any other unpleasant symptoms caused by the drug.

Ealing.

At the inaugural meeting of the Inverness Medical Society held in December, 1894, Dr. Mackay read a paper on a case of Myxœdema treated with Extract of Thyroid Gland and practically cured. Dr. Wilson Black contributed notes of two cases of Psoriasis in which the same remedy was administered; in one case it was successful, and in the other a temporary improvement resulted. We congratulate our brethren in Inverness on the foundation of a new medical society.

upon the thenar eminence. On Feb. 8th the bulla burst, discharging a thin, sanious fluid; a large slough, including the small muscles of the thumb, gradually came away, subsequently exposing the deep flexor tendons of the thumb and index-finger and the bare index metacarpal bone. On March 9th sensation was almost in abeyance over the palm and fingers, back and front, but over the dorsum of the hand as far as the metacarpo-phalangeal articulation it was fairly good. The thumb up to the line of demarcation had sensation almost unimpaired. Above the wrist sensation was normal. Flexion at the elbow and wrist was almost unimpaired, although the range of movement was limited owing to the prolonged constrained position. Power of flexion of the index-finger was lost, and of the remaining fingers it was present but modified; the power of extension was also modified. Massage of the arm and forearm, with frequent application of static electricity and the interrupted current, was persevered with. On the 15th the gangrenous process having entirely ceased and free circulation being evidently established, the thumb was amputated through the metacarpo-phalangeal joint, and, the patient being under an anæsthetic, advantage was taken to forcibly flex the elbow and break down adhesions. The amputation flaps maintained a healthy appearance, and the wound gradually healed, the large ulcer at the base of the thumb granulating healthily and quickly. On May 1st the man returned to work and was able to use his hand at his ordinary occupation. He has continued at his work, and, beyond the inconvenience of the stiffened index-finger, is at no disadvantage.

Remarks by Mr. FENNER.—Deligation of the axillary artery for traumatic aneurysm is sufficiently rare to warrant me in publishing this case. The only alternative would have been to open the aneurysm, turn out the contents, and attempt to tie both ends of the artery, an operation fraught with great danger to the limb and to the patient in his then weakened condition.

ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

TWO CASES OF STONE IN THE BLADDER WHERE PRIMARY UNION OF THE BLADDER WOUND OCCURRED AFTER SUPRA-PUBIC LITHOTOMY; REMARKS.

(Under the care of Mr. F. PAGE.)

It is generally agreed that in the ideal operation for removal of a stone from the bladder by the supra-pubic route primary union of the wound is required. Much attention has therefore been given to plans of suturing which promised success. The suggestions are numerous, embracing the questions as to the best material for sutures, whether they shall be put into the vesical wall or not, whether the abdominal wound shall be sutured or left open, and if sutured, whether the various layers shall be united separately or included in one with the bladder wall. It is said that success has been obtained by these and by other methods whether drainage was employed or not, whilst primary union of the bladder wound without suturing has been obtained more than once. As a matter of experience, it is most important, before using any sutures, to gauge accurately the condition of the bladder wall and urine, and the surgeon who employs the method of wound treatment best adapted to the particular case and follows no rigid rule will obtain the best average of successes. We have seen the most disastrous results follow the use of sutures—cellulitis, peritonitis, septicæmia, and pyæmia,—and are therefore somewhat chary in recommending them unless the bladder and urine are almost or quite natural and the former not bruised by the stone when removed from it. For the notes of these cases we are indebted to Dr. D. N. JACKSON, house surgeon.

CASE 1.—A man aged thirty years was admitted to the infirmary on June 10th, 1894, with symptoms of stone in the bladder of seven years' duration. The urine was thick and offensive and contained pus. The patient micturated with considerable pain every quarter of an hour. On June 12th a uric acid stone weighing two ounces and five drachms was removed supra pubem. No suture was introduced into the bladder wound; but the skin and muscles were sutured with fishing gut, only a small portion of the wound at its lower extremity being unclosed. A

soft catheter was secured in the bladder. Two days after the operation, owing to a slight urethritis, the catheter had to be removed, and the patient was taught to pass it for himself, which he did every two hours at first, and at lengthening periods till the wound was soundly healed. On the 21st urine was passed voluntarily, but the use of the catheter was not wholly discontinued till July 2nd.

CASE 2.—A youth aged eighteen years, who had had symptoms of stone for five years, was operated upon on June 23rd, 1894, and a large mulberry calculus weighing one ounce and seven drachms was removed supra pubem. Similar treatment was adopted in this case as in the last, with similar result, no urine at any time escaping in either case from the wound after the operation.

Remarks by Mr. PAGE.—The point to which I wish particularly to direct attention in these two cases of supra-pubic lithotomy is that, though the bladder wound was not sutured, no urine escaped through the wound during the progress of recovery. It all passed by the urethra. I have succeeded in obtaining the same result in a child on more than one occasion without suture of the bladder, but I have never before quite succeeded in the adult. In the first case the urine was offensive at the time of operation, and the stone was large and of an awkward shape. The second case was a more favourable one, the urine being quite sweet, and I do not see why similar results should not be generally obtained.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Illustrations of some Modes of Death from Ovariectomy.

An ordinary meeting of this society was held on Tuesday, Jan. 8th, the President, Mr. J. HUTCHINSON, F.R.S., being in the chair.

In opening the meeting the PRESIDENT made the following announcement. That with a view to extending the scope of the discussions and the usefulness of the society the Council had arrived at the following resolutions. 1. That papers accepted for reading be thereby accepted for publication either in the Transactions or in the Proceedings, as may be determined by the Council subsequently to the reading. 2. That the Transactions be published in three parts during the year (viz., on Feb. 1st, May 1st, and Aug. 1st, as well as annually), and that it be optional to the Fellows in which form they receive the Transactions. 3. That papers be issued separately (for sale by the society only) as early as possible after the issue of the part, at a price to be affixed to each. 4. That the papers be printed before discussion, and be obtainable (in proof) on application at the society's rooms. 5. That attention be drawn to the fact that the President may direct an author to read his own paper. 6. That some of the ordinary meetings be devoted to discussions and demonstrations on special subjects, to be introduced by a short paper or papers by Fellows of the society or others at the request of the Council, and that a small standing committee be appointed to arrange for these meetings and to draw up regulations respecting them.

Dr. JOHN D. MALCOLM read a paper on *Illustrations of some Modes of Death from Ovariectomy*. After referring to certain instances in which he had not operated on patients having tumours which he believed to have originated in ovarian tissue, Dr. Malcolm read the histories of all the cases of death from ovariectomy that had occurred in his practice to date. These were as follows: 1. A dermoid tumour ruptured into the bowel. At the operation a portion of the tumour inseparable from the sigmoid flexure was left on it, and fixed outside the peritoneum through an opening made for the purpose in the left groin. Symptoms of obstruction of the bowel began on the third day, after which the groin wound became offensive. Death occurred on the sixth day. After death there was no sign of general peritonitis. There was an obstruction formed by an adhesion of the healthy small bowel to the ovarian pedicle. This was on the right side. On the left side there was suppurative round the groin wound, limited by peritoneal adhesions. 2. A ruptured tumour, with papilloma fungating in and on it. About a year before Dr. Malcolm saw the patient her abdomen had

Mr. ALBAN DORAN said that the object of recording fatal cases at the present time was very different from that of thirty years ago, when the operation was then on its trial. Thanks to Sir Spencer Wells and a few others ovariotomy was now firmly established, and the object of investigations like the present was to answer the question, How is it that cases are ever fatal? He divided the causes of a fatal result into preventable and unpreventable. In the former category he

Dr. MALCOLM, in reply, admitted the difficulty of determining whether a heart was strong enough to overcome complications which could not be foreseen, though he recognised the state of the heart as having an important influence on the case. Though he did not see great objections to ovarian cases being put in general wards, he thought a death after operation would have a demoralising effect on others who were waiting their turn.

G. E. HERMAN, President, being in the chair.

Dr. JOHN SHAW read a paper on Peritonitis: its Nature and Treatment. He gave notes of two cases, the one of acute peritonitis of undoubted septic origin, the other presenting the symptoms of obstruction of the bowels following ovariectomy. In the first case death seemed to be hastened by a dose of opium, presumably from its effect in diminishing the elimination of the poison; and in the second case the strong presumption was that death was primarily due to the absorption of poison from the gastric mucous membrane. With this experience, Dr. Shaw, regarding the fatal issue as essentially toxic in origin, determined on a plan of action in any succeeding case which might present itself. Two such cases were briefly described where the treatment was successfully carried out. The course of action indicated was—(1) to limit as far as might be the formation of the poison; (2) to eliminate it when formed as quickly as possible, or at least to destroy it; and (3) to support the patient's strength during these processes. To secure these ends Dr. Shaw advocated the application of warm antiseptic compresses to the abdomen; the provision in suitable cases of drainage from the peritoneal cavity; persistent effort to evacuate the bowels, and pending this, as far as might be, the disinfection of the intestinal contents and the

HARVELAN SOCIETY C

[illegible]

Shaw directed to the title of the paper. It seems correct to speak of peritonitis as a local inflammation arising from the trivial to the serious. The difference between different cases is due to the nature of the inflammation. Bacteriologic examinations merely set up a mild inflammation, for example. Dr. Shaw thought that death was due to absorption of infective material from the stomach (as Dr. H. Horrocks) thought the cause of death was the occurrence of the nervous system through the spine. Again Dr. Shaw seemed to deprecate the term "peritonitis," but optimism and its derivatives are necessities in certain forms, such as what Dr. Horrocks termed "peritonitis." Dr. Horrocks mentioned the nature of the uterus where opium had been given. Dr. Shaw had noted a statement by Mr. Dorr that the effect of an case of peritonitis was that the effect that in the present would recur, but that the term. This statement was incorrect. It was not an opinion question whether to disturb the uterus. He asked Mr. Dorr that it was very common for him to puncture after abdominal surgery, the wound being liable to be perforated.

Dr. WHITE thought it was clear that the last
was not a case of peritonitis, but of paratyphoid
fever, the result of handling the
the remarkable fact that though the bac-
terium was perfectly harmless in health, it
became virulent when the fever was in any way de-
veloped. The cause of passage out of the bowel into the
blood and of causing septicaemia, including
the disease (typhoid) and others occurred thus
as a result of this "parasitosis." He (Dr.
White) with this, and thought it was possible that
there were some cases from absorption of the pro-
ducts, the patient escaping the more fatal
effects of the bacterium now in the meanwhile successful-
ly killed the bacterium now advocated in many cases
of typhoid and has become established as responsible
for the manner free immunities into the bowels and
the blood stream. He thought that, as certain
cases of fever might be in a state of toxic contraction
of the bowels was exaggerated, it was not wise to give
the dose so that it should always be combined with

the question of arterial tension as
the cause of these operations among "ner-
vous" is the theory that the contraction of
the arteries in the limbs was a result of the
anæsthetic dose and of impure blood. "The view
that the pulse in this case was due to defec-
tion was not consistent with Mr. Macdonald's
theory. The latter believed that the pulse
was very strong, was of course not
the same as the artery increased, during fever, and
that the various comments which he pre-
sented to the law, seemed to be greater
than a simple operation rather than on the
day, when the pulse changes were most

regular washing out of the stomach; and hypodermic injections of strychnia and digitaline, and the inhalation of oxygen.

Mr. DORAN said that none of the cases were simply instances of peritonitis. The first was septicæmia after disturbance of a suppurating focus. There was little evidence that the dose of opium mentioned did much harm. In the second case the main symptom was obstruction; the abdomen had been opened a few hours after operation and the pedicle fixed to the parietes, strain being designedly put on the broad ligament. In the third case the clinical symptoms mainly indicated obstruction. Clear serum escaped in quantities through the tube. The appearance of clear serum was an indication for removing the tube, otherwise the flow might go on indefinitely. The fourth case was very complicated, bronchitis set in, the omentum prolapsed on the fifth day, the next day the wound was opened up and sloughy omentum removed, and a valvular communication between the peritoneum and surface existed. Mr. Doran had found that whenever flatus accumulated and did not come away spontaneously a turpentine enema answered well. After the confined flatus escaped other bad symptoms usually disappeared. He had recently observed that in a case under his care where bronchitis set in, the grave pulmonary symptoms abated and ceased when the flatus came away. Warm water and bicarbonate of potassium acted well in clearing the stomach.

Dr. HORROCKS objected to the title of the paper. He did not think it correct to speak of peritonitis as a toxæmia. Cases of peritonitis varied from the trivial to the rapidly fatal. The difference between different cases depended on the cause of the inflammation. Bacteriology showed that certain microbes set up a mild inflammation, others a virulent one. Dr. Shaw thought that death was due to absorption of putrefactive material from the stomach and bowels. He (Dr. Horrocks) thought the mode of death indicated disturbance of the nervous system through the solar plexus. Again, Dr. Shaw seemed to deprecate the use of opium in peritonitis; but opium and its derivatives were the very best remedies in certain forms, such as what used to be called "traumatic peritonitis." Dr. Horrocks mentioned a case of rupture of the uterus where opium had been of great service. Dr. Shaw had quoted a statement by Mr. Lawson Tait to the effect that if in cases of peritonitis the bowels could be opened the patient would recover, but if not she would die. This statement was incorrect. It was often a most important question whether to disturb the bowels or not. He agreed with Mr. Doran that it was very important to get rid of flatus, particularly after abdominal section, on account of the wound being liable to be burst open.

Dr. AMAND ROUTH thought it was clear that the last three cases were not cases of peritonitis, but of paralysis of the bowels ("pseudo-ileus"), the result of handling. He alluded to the remarkable fact that, though the bacterium coli commune was perfectly harmless in health, it became virulent when the bowel was in any way diseased, and was then capable of passing out of the bowel into the blood and tissues and of causing septicæmia, including septic peritonitis. Olshausen and others believed that this happened as a result of this "pseudo-ileus." He (Dr. Routh) agreed with this, and thought it was possible that a sapremia arose in some cases from absorption of the products of the bacilli, the patient escaping the more fatal septicæmia if treatment were in the meanwhile successful. He mentioned the treatment now advocated in many cases where septicæmia had not become established of reopening the abdomen and making free incisions into the bowels and evacuating their contents. He thought that, as certain lengths of the bowel might be in a state of tonic contraction while the rest was exhausted, it was not wise to give strychnia alone, but that it should always be combined with atropine.

Mr. MALCOLM dealt with the question of arterial tension as a result of operations, abdominal operations among others, and objected to Dr. Shaw's theory that the contraction of the vessels found in the febrile state was a "revolt of the system against the circulation of impure blood." The view that the hardness of pulse in this state was due to deficient kidney secretion was not consistent with Mr. Malcolm's observations. The kidney secretion was of course not diminished, but very greatly increased, during fevers, and the diminution of the watery constituents, which he presumed was referred to by Dr. Shaw, seemed to be greatest immediately after an aseptic operation rather than on the second or third day, when the pulse changes were most

marked. He (Mr. Malcolm) believed that during the healing of a wound contraction began in the peripheral vessels, and that it increased in intensity, and extended from these small vessels to larger ones in proportion to the severity of the inflammatory fever, reaching the maximum of extent and intensity on the second or third day. About this time distension of the bowels might begin, producing by increased mechanical opposition still further reflex contraction of the vessels throughout the body, and thus might altogether deprive the tissues of their blood-supply and be the actual cause of death. He criticised the description of the cases in the paper as peritonitic, and considered that when the patient was constantly sick absorption from the stomach was in abeyance, and that the occurrence of such absorption meant that the patient was getting better. He was of opinion that, where the intestines were distending and the patient was sick, food which was rejected did more harm than good.

Dr. GIBBONS wished to add his testimony to that of Dr. Shaw as to the great value of subcutaneous injections of digitaline and strychnia, and he would also include atropine, in the treatment of peritonitis. He mentioned a case where this method had, he believed, saved the life of a patient. He considered it infinitely superior to extra stimulation by alcohol.

The PRESIDENT agreed with the speakers who had said that the title of Dr. Shaw's paper was too comprehensive. He (the President) thought that some such title as the "Advantage of Washing out the Stomach in cases of Peritonitis" would have better denoted the scope of the paper. He thought it was now established that peritonitis was produced by micro-organisms. The poisoning they brought about was only an effect of the micro-organisms, but not the essential cause of the disease. He was quite prepared to accept Dr. Shaw's statements as to the benefit of washing out the stomach in peritonitis when vomiting was copious. He did not accept Mr. Lawson Tait's statement that peritonitis could be prevented by purging the patient; but he quite believed that if the bowels could be got to act the patients were the better for it. Mr. Treves had shown that in those cases of peritonitis in which diarrhoea was present the mortality was less than in those where there was constipation. The treatment of peritonitis was according to its cause. If it depended on disease of the stomach or bowels it was important that the diseased part should be kept at rest, and therefore opium was indicated to restrain peristaltic movement; but when peritonitis arose from disease of the uterus or its appendages, the alimentary canal being healthy, there was not the same utility in giving opium. It was in such cases beneficial in relieving pain, but in no other way.

Dr. JOHN SHAW, in reply, acknowledged the justice of the criticism on the title of his paper. He explained certain points which he thought had been misunderstood by the speakers.

The following specimens were exhibited:

Dr. CULLINGWORTH: Cystic Enlargement (probably Pyosalpinx) of Tube.

Dr. STEVENS: Fœtus in which the Urethra was absent, with other abnormalities.

Dr. LOTT: Fœtus Papyraceus.

Dr. AMAND ROUTH: Cancerous Uterus and Parovarian Cyst removed together per vaginam.

Dr. DES VŒUX: Circumscribed Clot in Placenta.

HARVEIAN SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Jan. 3rd, the President, Mr. G. EASTES, being in the chair.

Mr. G. C. WILKIN showed a boy aged ten years with a Deflexion of the Nose. There was a history of a blow on the nose two years ago. When he first came under observation there was a marked deflexion of the nose to the right. Grant's septal splint was at first used, but was found to increase rather than reduce the error. A splint was made consisting of a band fitting round the head, from which two metal rods fell, one on either side of the nose, carrying a movable plate, which could be screwed up to any degree of pressure. This effected a considerable amount of improvement.

Mr. EDMUND OWEN showed a girl aged eleven years from whom he had removed the upper third of one Fibula

Dr. CAGNEY showed cases of Raynaud's Disease and Muscular Atrophy and of Tabes.—In reference to Dr. Cagney's case of Raynaud's disease, Dr. JAMES TAYLOR said it was, in his experience, unusual for the symptoms of Raynaud's disease to be aggravated by a higher temperature. This patient did not seem to suffer from the intense pain which in so many cases followed a change of temperature. He ventured to think that in the case mentioned by the President there was present some disease of the spinal cord determining the vaso-motor symptoms and also the peculiarly perverted sensibility. The condition in which cavities were present in the cord—syringomyelia—was accompanied by vaso-motor symptoms, muscular atrophy, and loss of sensibility for pain and temperature. In regard to Dr. Cagney's case of "muscular dystrophy," Dr. Taylor thought it was a pity to apply such a term to this case. The term was now so widely used as descriptive of cases of perverted muscular nutrition without change in the central nervous system—cases of pseudo-hypertrophic or idiopathic muscular atrophy—that its application to cases other than those was apt to be misleading.

Dr. COLMAN read a paper on the Treatment of Epilepsy. After referring shortly to many barbarous methods formerly in vogue in the treatment of the disease, he referred to the importance of preventing fatal accidents during the fits, such as choking from vomiting, and suffocation from the patient

Dr. CHAPMAN read a paper on the *Rôle of Alcohol in the Treatment of Heart Disease*. While recognising the value of alcohol in appropriate cases, and on particular occasions, he protested against its prescription in cardiac cases as a matter of routine. It was shown that in some cases alcohol was absolutely harmful, and in none should the patient be left to decide as to the amount and frequency of the dose. In fact, he considered that some cases of failing heart were more benefited by purging or bleeding than by stimulation. Dr. SYMONS ECCLES referred to the existence of dilatation of the left ventricle in cases of neurasthenia, and in such cases he found that the action of alcohol was advantageous, but of course its use must not be abused.—Dr. C. PORE drew attention to the use of the tincture of *Cactus* in cases where the heart was beating forcibly, and which, therefore, were unsuitable for alcohol. He considered that the drug was of value.—Dr. CHAPMAN replied.

LOVETT, President, being in the chair.

D. T. M. LEGGE read a paper on Some Points of Difference between English and Continental Methods of Municipal Sanitary Administration based on personal observations during several special visits to Copenhagen, Christiania, Stockholm, Brussels, Paris, Berlin, and several other French and German towns. There were, he considered, many things in which we should do well to imitate their more perfect

SHEFFIELD MEDICO-CHIRU

much resembling that most of their shortcomings are owing to the exigencies of military defence, and in fact of special police health legislation, and in restriction of the sanitary to the police service, which was not present in France. In Germany, however, Dr. Pilsner held a position similar to that of medical officer in chief of a large urban or contracted military district here. In Scandinavia the sanitary was very much expanded, on the duties of the medical officer being most for any one man, even with an ample staff of assistants. He was also public analyst, recorder of births and deaths, medical assessor to the law on matters of school hygiene, factories, etc., and had a variety of vaccination, prostitution, etc. Not only did he carry all preventive diseases were notifiable, but cases arising from twenty to twenty-five, and acted as codes of comprehensiveness, giving on a great mass of facts likely to aid in tracing and curbing the spread of the disease. In Norway the contagious diseases acts had been repealed, and notwithstanding every effort intended, but with unsatisfactory results. In Brussels, sprays of walls and ceilings and water closets and furniture with systematic solution of an 10 per cent. mixture, operations which, not occupying much time, rendered provision of temporary accommodations impossible, and to all results had ever been seen. In Berlin, however, should the epidemic be seen in the walls were covered with bread and three times a day 5 per cent. carbolic acid solution. All other measures were conducted by steam, and in Denmark erected in their own towns, lack of Copenhagen supply of a few hundred apartments complete with water and fittings for 10 to 15 families, arrangements to city could compare favourably for the most perfect isolation hospital was that of Berlin. In Germany systematic vaccination had now nearly reached its final point. School hygiene received attention, the children being inspected every fortnight for a medical man and a dentist, and hearts and on matters of sanitation, infectious diseases, and first aid to accidents. Public slaughter-houses, and first aid to contagious diseases, were not possible, were very common, and in the chief German and northern capitals, and in the whole of Stockholm, and in a lake water of the city, the centimetre were condemned, and the discovery that the green algaed film which grew on the surface of a sand filter had alone the water had within twenty-four hours after the removal of the water had been rejected, while all filters were used as a protection against frost. The water of the Sennar was adopted in Brussels, Berlin, and all other towns of Germany. Pails were still used in the collection of the urine, and both systems existed in Paris, and in the Sennar, and of the Sennar near the Sennar was practically. The entire sewage of the city was collected with the highest still and with military engines. What was once a muddy waste with a few stunted trees and public institutions, populations enjoying the health of London (Manchester) then read a paper on the history of infection in Prussia, in which, while freely admitting the communicability and, under certain conditions, the communicability of tuberculosis by inhalation or by contact, he maintained that there was at present a tendency to the view that there was at present a tendency to the view that the more fact of its communicability a disease was oral, sexual, impracticable, and calculated to cause political parties should not only be forbidden to be isolated at home, and in fact, shunned as a social disgrace. The communicability of phthisis had been proved here and elsewhere, but it had received its death blow from the discovery of the bacillus by Koch and the successful researches of Cornet. Dr. Ransome had

methods, remembering that most of their shortcomings were owing to the exigencies of military defence, and the want of special public health legislation, and the subordination of the sanitary to the police service, which was most complete in France. In Germany the *Stadt* or *Kreis Physikus* held a position similar to that of the medical officer of health of a large urban or combined rural sanitary district here. In Scandinavia the sanitary services were highly organised, but the duties of the medical officer were too much for any one man, even with an ample staff of expert assistants. He was also public analyst, registrar of births and deaths, medical assessor to the law courts, inspector of schools, asylums, factories, &c., and had the supervision of vaccination, prostitution, &c. Not only infectious but nearly all preventable diseases were notifiable, the schedules comprising from twenty to twenty-five, and the forms were models of comprehensiveness, giving on a post-card a mass of facts likely to aid in tracing and checking the spread of the disease. In Norway the Contagious Diseases Acts had been repealed, and notification strictly enjoined instead, but with unsatisfactory results. Except in Brussels sulphur fumigation had long been abandoned, spraying of walls and ceilings and washing floors and furniture with sublimate solution (1 in 1000) being substituted, operations which, not occupying more than an hour, rendered provision of temporary accommodation superfluous, and no ill results had ever been observed. In Berlin, however, should the sublimate be objected to, the walls were rubbed with bread and then saturated with a 5 per cent. carbolic acid solution. All clothes and bedding were disinfected by steam, and in Denmark even villages had their steam ovens, Reck of Copenhagen supplying a very efficient apparatus complete with boiler and fittings for £88. For ambulance arrangements no city could compare with London, but the most perfect isolation hospital was that at Stockholm. In Germany systematic revaccination had now practically stamped out small-pox. School hygiene received the fullest attention, the children being inspected every fortnight by a medical man and a dentist, and leaflets &c. on the elements of sanitation, infectious diseases, and first aid freely circulated. Public slaughter-houses, without which a complete inspection of meat was not possible, were very general, those at Berlin being simply perfect. Public water-supplies were in the chief German and northern capitals examined every week, not only chemically, but bacteriologically; and while Stockholm rejoiced in a lake water of almost absolute purity, at Berlin all waters yielding 100 colonies to the cubic centimetre were condemned, and since Koch's discovery that the green algoid film which formed on the surface of a sand filter had alone the power of arresting bacteria, the water that had passed through a bed within twenty-four hours after the renewal of the surface had been rejected, while all filters were vaulted over as a protection against frost. The water carriage of excreta was adopted in Brussels, Berlin, and all the larger towns of Germany. Pails were still used in the Scandinavian capitals, and both systems existed in Paris. The condition of the Seine below Paris and of the Senne near Brussels was inexpressibly foul, but the purity of the Spree at Berlin was remarkable. The entire sewage of that city was treated by irrigation and filtration on 12 000 acres of farms, conducted with the highest skill and with military precision. What was once a sandy waste with a few stunted pines was now a vast garden yielding heavy crops of corn, roots, grass, vegetables, and fruit, and studded with villas, cottages, and public institutions, populations enjoying the best of health.

Dr. RANSOME (Manchester) then read a paper on the Limits of Infection in Phthisis, in which, while freely admitting the inoculability and, under certain conditions, the communicability of tuberculosis by inhalation or by ingestion, he maintained that there was at present a tendency to ignore those conditions which were essential to infection and to raise out of the mere fact of its communicability a scare which was cruel, useless, impracticable, and calculated to disorganise family and social life. A recent writer had demanded that phthisical patients should not only be forbidden to marry, but should be excluded from churches and all places of public resort, be isolated at home, and, in fact, stunned and treated as lepers. The communicability of phthisis had long been a popular belief in Southern Europe, and had had its adherents here and elsewhere, but it had received its greatest impulse from the discovery of the bacillus by Koch and the statistical researches of Cornet. Dr. Ransome had,

however, constantly maintained that it was a grave error to ignore the conditions without which infection was scarcely possible. He had shown that there were in all large towns infected areas, constituted such by dampness, want of air and light, with overcrowding, &c. He had even known persons in whom the disease remained in abeyance so long as they resided as patients or as servants in a Consumption Hospital, but was rekindled soon after their return to their homes in the city. Hirsch had pointed out that in Syria, Egypt, and Algeria the nomad Arabs were exempt, while the inhabitants of towns suffered; and in our own country agriculturists were freer than the town population, while fishermen enjoyed the greatest immunity. He and Dr. Delépine, and subsequently Dr. Heron, had carried out experiments which tended to show that, while dried sputa retained their infectivity for long periods in darkness, exposure to air and light soon rendered them inert. He would, of course, enjoin the careful disposal and destruction of the sputa, but far more would he insist on the freest light and ventilation, remembering that the reduction in the death-rate from phthisis, representing a saving of 30,000 lives per annum, was wholly due to improved sanitary conditions. Drs. Seaton, Whitelegge, and Willoughby, Mr. Shirley Murphy, and others took part in the discussion.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Cholecystotomy. — Double Optic Atrophy. — Sarcomatous Tumours. — Removal of the Parotid Gland. — Exhibition of Specimens. — Rectal Etherisation.

A MEETING of this society was held on Dec. 20th, 1894, the President, Mr. MAKEIG JONES, being in the chair.

Dr. SINCLAIR WHITE exhibited and related particulars of: 1. A woman on whom he had performed Cholecystotomy for severe and persistent attacks of Hepatic Colic. Repeated examinations of the fæces failed to show biliary calculi, and the attacks were getting worse. Each attack was followed by jaundice. Twenty-seven stones were removed from the gall-bladder and two were crushed in the common bile-duct. The woman made an excellent recovery, and had been free from pain since the operation. 2. A boy nearly blind from Double Optic Atrophy due to a Subdural Abscess, which discharged itself six weeks after the onset of severe symptoms through the anterior fontanelle. 3 and 4. Sarcomatous Tumours removed from the Coccyx of a woman seventy-two years of age, and the Parotid of a woman twenty-six years of age. The latter tumour had grown very rapidly and had invaded the neighbouring lymphatic glands.

Mr. RICHARD FAVELL showed: 1. A large Multilocular Ovarian Cyst containing fifty-three pints of fluid which he had removed from a woman fifty-five years of age. 2. A Piece of Retained Placenta which had caused recurring attacks of severe hæmorrhage till its removal eight weeks after confinement. — Mr. WEST JONES gave particulars of a large Gall-stone passed per anum, and showed the specimen. — Dr. ARTHUR HALL showed specimens of Cystic Calculi.

Dr. KEELING showed specimens of Tubal Mole, Ovarian Dermoid Cyst, and Substance removed from Uterus four months after incomplete abortion, and gave particulars of the cases.

Mr. BERNARD STEDMAN read a paper on Rectal Etherisation. He said that, though Pirogoff employed this method fifty years ago, it was only quite recently that it had been revived by Dr. Dudley Buxton. Mr. Stedman had lately administered ether by the rectum in about twenty cases of operations about the mouth in the Sheffield Public Hospital, and so far the results had been extremely satisfactory. The method used was that of placing a vessel containing ether in water at 120° F. and conducting the vapour through a piece of indiarubber tubing to the rectum. There was little or no struggling during the administration. The disadvantage was the length of time taken to anaesthetise some patients. For several cases it was over half an hour. This could be overcome by giving ether by the mouth as well as the outset. When this was done the temperature of the water need not be above 110°, this temperature being sufficient to keep the patient under by the rectum alone when once fully anaesthetised. The after-effects in Mr. Stedman's cases were very slight. There was no sickness in half the cases, and in two or three there was a little diarrhoea with a discharge of mucus for several days.

are dealt with in Lectures V. and VI. The Respiratory System, the principles of ventilation, and the main features of diseases of the throat and lungs occupy the two following lectures, and these are succeeded by descriptions of the Functions of the Kidneys, Skin, &c. Three lectures are devoted to the subject of Temperature, Infection, and Fevers, and the final one treats of the Nervous System. No one can peruse the book without being struck with the vast amount of really useful information which Dr. Anderson conveyed within small compass, and also with the methodical manner in which he traversed the large field before him. Such lectures must have been of good service to his audience and cannot have failed to interest them. In their present form they constitute a text-book which will be of service to the probationer and one not wholly to be disregarded by him who undertakes a like duty to that which the author so well performed. For the art of elementary instruction in such a subject as physiology, and of combining this with the application of its truths to the practice of sick-nursing, has seldom been so well manifested as by this valued physician and teacher, whose character and life are faithfully sketched in the memoir affixed to this volume—a memoir extracted from the last presidential address delivered to the Royal College of Physicians of London by Sir Andrew Clark, whose knowledge of James Anderson, as pupil and colleague, was deep and true.

Diseases of the Skin. By W. ALLAN JAMIESON, M.D. Edin. Fourth edition. Edinburgh: Young J. Pentland. 1894.

A WORK which has reached a fourth edition has passed beyond criticism as to its scope and the success of the author in realising the aim he had before him, and it only remains for the critic to point out how the new edition differs from the old and to briefly appraise the new material. The author claims to have made an exhaustive revision and to have almost rewritten some chapters, such as those on Lupus and Ringworm. He has added two new chapters on the Disorders of the Vascular System and the Treatment of Syphilis, and has incorporated sections on the Hygiene of the Hair and Nails, the Agency of Micro-organisms, on Darier's Disease, Hidrocystoma, Erythema Induratum, Lichen Neuroticus, Epidemic Exfoliative Dermatitis, Corns, Elephantiasis, Epithelial Cystadenoma, Sarcoma, Mycosis Fungoides, and Actinomycosis. This enumeration shows that the author is gradually extending the scope of his work in the direction of completeness, the earlier editions having never pretended to be a complete exposition of the subject even within the limits of clinical description. Three new coloured illustrations of Pityriasis Maculata, Xanthoma Diabeticorum, and Mycosis Fungoides replace respectively Lichen Verrucosus, Circumscribed Scleroderma, and Tuberculosis of the Skin, and we may say at once, much to the advantage of the present edition, that the originals of the new illustrations are probably truer to nature, and there is marked improvement in the style of reproduction. We hope that in future editions one or two more plates may be improved out of existence—notably, acne varioliformis as at present depicted. Lichen neuroticus is the name given by Unna and Dühring to the complex of symptoms which they consider represent the lichen ruber of Hebra and not corresponding, they think, to the lichen ruber acuminatus of Kaposi or the pityriasis rubra pilaris of Devergie; it seems a pity to further complicate the subject by inventing a new name.

Epithelial cystadenoma (Besnier) is the name selected by the author out of a host of synonyms for a rare affection which was originally described by Kaposi under the name of lymphangioma tuberosum multiplex, and consists of small epithelial lined cysts containing a colloid material which are embedded in the skin and project slightly.

Hidrocystoma is the name given by Robinson of New

York to a rare and not very important affection of the sweat apparatus in which deep-seated sago-like grains are scattered over the face.

The article on Mycosis Fungoides is a fairly full one, and is illustrated by the description and plate of a good case of the rare form first described by Kaposi as lymphodermia perniciosus. The author, however, is in error in stating that mycosis fungoides was described for the first time in 1832 by Alibert and figured in the following year in the second edition of his Atlas. Alibert gave a plate and description of the case in the first edition of the Atlas in 1814, Plate 36, only he called it there "Pian fungoide," and changed the name in the later edition.

It will thus be apparent that the author no longer contents himself with the exposition of the commoner forms of skin disease, but that in each successive edition he gives his readers the benefit of his widening experience in diagnosis and treatment, and we can therefore predict as much success for the present as for the past editions, on which it is in many respects an advance.

Practical Urinalysis and Urinary Diagnosis. By Dr. CHARLES W. PURDY. Philadelphia: F. A. Davis and Co. London: F. J. Rebman. 1894.

THE class of book of which the present volume is one of the latest additions has enormously increased of late years. Formerly the examination of the urine was only treated of in general text-books on medicine and surgery, and the student had frequently to search several volumes before he discovered the information he desired; but now there are many works on urology, and still more on clinical pathology. Such books are very valuable, but there seems a great tendency to an over-production. In the volume now under consideration there is a large amount of useful information collected together in a readable and convenient form, and a special effort has been made to bring out prominently the relations of the chemistry of the urine to physiological processes and pathological facts. This method is certainly to be highly commended, for it teaches not only how to detect, isolate, and determine the constituents of the urine, normal and abnormal, but also how to determine the presence of disturbed physiological processes, to detect the presence of pathological changes, and to measure the degree of both.

The book is divided into two parts. The first treats of the analysis of urine, including both the normal and abnormal constituents. The various chemical processes are well described, and the author very wisely points out in each case which method has given the most satisfactory results in his hands. The second part "aims at a concise description of the special features of the urine that indicate the presence of special pathological processes in progress in the economy, whether they be local or general, medical or surgical, together with a brief enumeration of the leading clinical symptoms of each disease, and in most cases an epitome of their nature and etiology." Dr. Purdy has accomplished his object in a most satisfactory manner and is to be congratulated on the work produced.

The book is well illustrated, and although the great majority of the illustrations are borrowed they are none the less valuable on that account.

LIBRARY TABLE.

Diagnosis, Differential Diagnosis, and Treatment of Diseases of the Eye. By A. E. ADAMS, M.D., Instructor in Diseases of the Eye in the Post-graduate Medical College, New York. London and New York: G. P. Putnam's Sons. 1894.—Each page of this little book deals with two of the principal disorders of the eye, these pairs being selected on account of their having some points of resemblance. Each

of their names stands at the head of a column consisting of brief enumerations of the leading symptoms, and capital letters are used for those features which distinguish the two morbid conditions from one another. For instance, interstitial keratitis and ulcer of the cornea are grouped together on account of the loss of vision, pain, photophobia, and circumcorneal injection common to both, and are distinguished by the former having the cornea smooth and lustreless with a white-grey opacity, and by the latter having an excavated cornea with a yellow-grey opacity. In the words of the preface, the work is "designed more especially for the active practitioner, who does not claim to be an ophthalmologist." It is, no doubt, a concise and convenient summary of ophthalmic diseases and their treatment.

Spinal Curvature and Ankward Deportment: their Causes and Prevention in Children. By Dr. GEORGE MÜLLER, Professor of Medicine and Orthopedics, Berlin. English edition by RICHARD GREENE, F.R.C.P. Edin. London: The Scientific Press, Limited. 1894.—The majority of parents who are solicitous for their children's success in life have before their minds a mistaken educational ideal, according to which too much is taught at a tender age and an ever-increasing amount of study is compressed into the school period. Dr. Müller utters an emphatic warning against thus overloading a child's mental faculties, and proclaims the need for systematic attention to physical training and the symmetrical development of the bodily form. He points out that many children are predisposed to spinal curvature by hereditary tendency and by constitutional weakness, but that far the most common cause of the deformity is the position in which writing is taught. He recommends that the seats used in school by children should allow the soles of their feet (not the toes only) to rest flat on the floor and should be provided with sloping backs. The writing-table should be well-sloped, and its edge should overhang the front of the seat. Handwriting should be upright and not slanting. The author's precepts are largely directed to the prevention of curvature; for the correction of it he recommends a variety of muscular exercises which are fully described and illustrated by engravings. His remarks and directions are practical and judicious and worthy of careful attention.

An Address on the Cultivation of the Speaking Voice. By Miss D'ORSEY, Lecturer in Elocution, King's College (Ladies' Department). London: J. Masters and Co. 1894.—An easy, distinct style of speaking and an effective delivery are accomplishments of no small value to their possessor in whatever walk of life he may be. On the other hand, an indistinct or too hasty speaker is a source of discomfort, not only to himself, but in even a greater degree to those who have to listen and perhaps may wish to learn. Miss D'Orsey's object is to call public attention to this question and to obtain a general recognition of the excellent results obtained by systematic and methodical "voice training." She is a daughter of the late Rev. Professor D'Orsey, and appears to have inherited some portion of her father's eloquence and educational attainments. The address is a short summary of the work accomplished by her in furtherance of the project.

Wintering in Egypt. By ARTHUR J. M. BENTLEY, M.D., and Rev. C. G. GRIFFENHOOF, M.A. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1894.—This is a record of personal experience which the authors have presented in the form of a brightly written and entertaining narrative. Having arrived at Alexandria they seem to have proceeded with the least possible delay to Mena House Hotel, about eight miles from Cairo, and close to the Great Pyramid. Here their headquarters were fixed and the period of their stay was agreeably passed in excursions and sight-seeing in the neighbourhood, diversified by expeditions to Cairo and Memphis. The work has none of the formality

of a guide-book or a diary, and no disquisitions on Egyptology beyond assigning the Pharaoh of Joseph to the shepherd kings and mentioning Menephtah as the Pharaoh of the Exodus. The proximity of Mena to the Great Pyramid naturally led the travellers to explore its interior, an enterprise which took place on Boxing Day, and provided materials for a picturesque description. The Sphinx was often visited, and there is a graphic account of its appearance. Dr. Bentley, who has for some years been resident at Mena during the winter months, contributes a most instructive supplementary chapter of about thirty pages, containing hints for invalids on the maintenance of health in Egypt. He strongly recommends that the journey should be made by the long sea passage from the Thames to Brindisi, at which port the traveller should go on board a steamer for Alexandria. The book is just such a one as the tourist should peruse before setting out and take with him on the voyage.

The Practical Guide to Algiers. By GEORGE W. HARRIS. London and Liverpool: George Philip and Son. 1895.—Algeria has of late years been increasingly resorted to by English tourists and invalids. There is no probability that it ever will have for us the political and antiquarian interest attaching to Egypt; but it is in point of time almost a week nearer to our shores, and the great extent of the country, together with the mountainous character of the interior, cause it to present some variety of climate and much diversity of natural feature. Public security is guaranteed by the strong military and civil administration which France has conducted for the last sixty years, and which has converted the piratical and turbulent natives into a law-abiding population. Algiers, the capital, is most conveniently reached from Marseilles, steamers passing each way three times a week, and covering the distance in about twenty-four hours. Mr. Harris's Guide, though of a size convenient for carrying in the pocket, contains a vast amount of information judiciously selected and well arranged. It is divided into three sections, treating respectively of Algiers itself, the environs, and the rest of the country. Each of these is elucidated by a map, that of the last section showing the whole country from Tunis to Morocco, and from the Mediterranean to the desert. Oran and Constantine are described, and also Tunis, which may be reached from Algiers either by rail or steamer. Minute directions are supplied for excursions, both by rail and diligence, to many places of interest, particular attention being given to Bliska, far to the southward, and Hammam-Meskoutine, where there are natural baths having a temperature of 203° F. As a preface the author prints a letter to himself from Lady Burton, wife of Sir Richard Burton, the celebrated explorer.

Transactions of the Clinical Society. Vol. xxvii. London: Longmans, Green, and Co. 1894.—This volume comprises the papers read and an abstract of the notes of cases shown before the society during its twenty-seventh session—October, 1893, to May, 1894. Nearly all the papers supply information about subjects (not infrequently of great rarity) of interest to the profession, whilst some suggest new methods of treatment. As might be expected, the number of surgical cases far outweighs the number contributed by the physicians, and shows in some way the progress of the surgeon's art during the year. We have published in the columns of THE LANCET abstracts of the proceedings of the society, and have also supplied notes of the discussions which have been held. In these transactions the discussions are not included; this in a majority of instances is very wise, but sometimes definite facts (not mere opinions) are contributed by members which would be useful if added for reference. The living cases shown and described by card were of uniform excellence, and the notes of them selected for publication are most useful for future reference. The book is judiciously

illustrated with chromo-lithographs and woodcuts which add to its value.
Tanner's *History of England*, *Biography*, and *History of the World*. London: Wm. and A. C. Black and Co.—Books of reference and of an almost indispensable to the general reader, a record of the numerous ramifications of aristocratic families, the changes of title caused by death and marriage, and the additions always being made, more especially in the series of the nobility. This volume, by its arrangement of its arrangement and the free use of small type, contains a large amount of information within reach of the reader, and forms a portable and convenient guide to the history of the nobility. As might be expected, the exterior is a matter of great importance.

John Johnson's.

LIQUID SULPHURETTED HYDROGEN.

In the use of gases nowadays is no more scientific than the use of liquids. Sulphuretted hydrogen has become a commercial undertaking, and is now used in large quantities for the purpose of obtaining in large quantities, but until now sulphuretted hydrogen was not a member of this category. For many years there is no more useful agent in the laboratory than sulphuretted hydrogen, and the use of sulphuretted hydrogen in the laboratory is a constant use for the determination and separation of metals. It is indispensable in the series of tests for the isolation and purification of many well-known bodies, for the separation of various acids, and for the preparation of various salts, and is prior to

the classification. Sulphuretted hydrogen is, in fact, one of the most useful reagents at the disposal of the chemist, and is used in the laboratory for the purpose of obtaining in large quantities, but until now sulphuretted hydrogen was not a member of this category. For many years there is no more useful agent in the laboratory than sulphuretted hydrogen, and the use of sulphuretted hydrogen in the laboratory is a constant use for the determination and separation of metals. It is indispensable in the series of tests for the isolation and purification of many well-known bodies, for the separation of various acids, and for the preparation of various salts, and is prior to

illustrated with chromo-lithographs and woodcuts, which add much to its value.

Whittaker's Windsor Peerage, Baronetage, and Knightage for 1895. London: Whittaker and Co.—Books of reference such as this are almost indispensable to the general reader on account of the numerous ramifications of aristocratic families, the frequent changes of title caused by death and succession, and the additions always being made, more especially to the various orders of knighthood. This volume, by the compactness of its arrangement and the free use of small type, contains a large amount of information within reasonable limits, and forms a portable and convenient guide for occasional use. As might be expected, the exterior is resplendent in scarlet and gilding.

New Inventions.

LIQUID SULPHURETTED HYDROGEN.

THE liquefaction of gases nowadays is no mere scientific possibility; it has become a commercial undertaking. Already we are familiar with liquid carbonic acid, nitrous oxide, and sulphurous acid as commercial commodities which may be obtained in large quantities; but until recently sulphuretted hydrogen was not a member of this useful category. Yet probably there is no more useful agent to the investigating chemist, the toxicologist, and the physiologist than sulphuretted hydrogen in the laboratory. It is in constant use for the determination and separation of metals, it is indispensable in the series of operations for the isolation and purification of many well-defined organic bodies, for the separation of toxins and for the purification of poisons (alkaloids, ptomaines) prior to

their identification. Sulphuretted hydrogen is, in fact, one of the most useful servants at the disposal of the chemist, analyst, and toxicologist. The convenience, therefore, of having at hand the pure gas contained in a cylinder, from which it may be steadily withdrawn, is too obvious to need further remark. Lecturers on chemistry, and especially practical chemistry, know full well the trouble and inconvenience attending the preparation of sulphuretted hydrogen from sulphide of iron by acting upon it with a dilute acid. The pure and dry gas is compressed into specially made steel cylinders, each containing one pound of liquid, equal to about eleven cubic feet of gas at atmospheric pressure. The cylinders have been tested to 1500 lb. per square inch, and the pressure when filled with liquid H_2S never exceeds 300 lb. per square inch. The valve has been especially designed for use in the laboratory. This

enterprise is due to Messrs. Baird and Tatlock, 14, Cross-street, Hatton-garden.

FLETCHER'S NON-LIGHTING-BACK BURNER.

It is evident that the use of non-lighting-back burners in gas fires is rapidly becoming the rule rather than the exception. Prior to the report of THE LANCET Special Analytical Sanitary Commission on Smoke Prevention and Perfect Combustion (III. Gaseous Fuel, Gas-Heating, and Gas-Cooking Appliances)¹ in which was pointed out the pressing need for a remedy for this defect, which is peculiar to atmospheric burners, we believe that such a device did not exist, or if it did its application was neglected in the case of gas fires, or probably it was of little practical use. Since the issue of this report we have noticed two burners, constructed in a special and slightly modified way in order to obviate this drawback. Still another example of the force and importance which makers of gas stoves evidently attached to our remarks on this defect, is afforded in the non-lighting-back burner which has recently been sent to us by Messrs. Fletcher, Russell, and Co., Limited, 115, Cheapside, E.C. In this burner the orifices are bound on either side by projecting cheeks of iron about half an inch high, while the gas itself is delivered through a gallery of slits immediately beneath the orifices and in the body of the burner, which contains the mixture of air and gas. We found on testing that the proportion of air mixed with the gas was rather less than that contained in a mixture which gives a steady, colourless, or slightly blue flame. In consequence of this, the flames exhibited white caps, but doubtless this could be easily corrected by careful adjustment of the injector. The main object, however, is secured, since all manner of attempts to cause it to light back, representing to an exaggerated degree the conditions which might obtain in practice, failed.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the committee of the Association of Fellows of the Royal College of Surgeons of England was held at 25, Grosvenor-street, W., on Wednesday, Jan. 3rd. In the unavoidable absence of the President, Mr. George Pollock, Mr. T. Holmes, Vice-President, occupied the chair. The minutes of the last meeting were read and confirmed. In reference to the almost identical resolutions sent in to the Secretary of the College on behalf of the Society of Fellows and the Association of Fellows for the meeting of Fellows called for Jan. 3rd, the Chairman stated that one of the members of the Executive Council of the Society of Fellows had called on him and suggested that it would be advisable that only one resolution should be proposed, and that this motion should be proposed by a member of the Society of Fellows and seconded by a member of the Association of Fellows. The committee of the Association approved of this course and requested Mr. T. Holmes to second the resolution of which Mr. Bennett had given notice, and to communicate this determination to Mr. Bennett. Mr. Gant had written to say that the state of his health absolutely prevented him from attending the meeting of the committee and that he could not be at the College meeting on Thursday. It was therefore considered expedient that leave should be obtained to withdraw Mr. Gant's resolution at the meeting.

¹ THE LANCET, Nov. 25th, 1893.

THE Princess Louise (Marchioness of Lorne), accompanied by the Marquess of Lorne and Lady Northesk, visited the Victoria Hospital for Children, Chelsea, last week, and took part in the distribution of toys and presents to the sick children.

THE LANCET.

LONDON: SATURDAY, JANUARY 12, 1895.

WHEN the Council of the Royal College of Surgeons of England fixed the first of the half-yearly meetings of the Fellows of the College for the first Thursday in January we anticipated that there might be some difficulty in securing and maintaining a quorum, especially if the business to be transacted proved to be of an uninteresting or uneventful character. That there were good grounds for these anticipations was shown at the commencement of the meeting of Fellows held on the 3rd inst. at 4 P.M. in the theatre of the College, an account of which appeared in our second edition last week. Some minutes elapsed before the quorum of thirty was obtained and the attendance never rose to fifty. Most of the Fellows who came, however, stayed to the end of the proceedings, the agenda containing topics of considerable interest and importance both to the Fellows and to the profession at large. The first item of the programme was the formal report to the Fellows of the answer of the Council to the resolution adopted at the last meeting of Fellows requesting the Council to take steps for obtaining the opinion of the Fellows on the mode of election to the office of President. Mr. HULKE, the President, who occupied the chair, reported that on July 30th the Council adopted the following resolution: "That the Council are not prepared at the present time to consult the Fellows or solicit their opinion through other means than the meetings of Fellows. They, however, point out that if any Fellow is anxious to test the opinion of the general body as to whether it is desirable to make any change in the present mode of election of the President it is open to him to submit a motion on the question to the meeting of Fellows in January or subsequently." No one rose at the moment to make any comment upon this reply; it was received *sub silentio*. In THE LANCET of Dec. 29th, 1894, we took occasion to demonstrate the fallacy involved in the latter part of this answer to the resolution of the Fellows, and expressed our regret that the Council had not complied with their request and undertaken the canvass of the Fellows in regard to the mode of election of President. Our words found an echo in more than one quarter at the meeting in connexion with the results of the canvass made by the Society of Fellows and reported by Mr. HERBERT PAGE.

This canvass embraced those Fellows only resident in Great Britain. A thousand voting papers were sent out, and 468 papers were returned, but for some cause or other 50 of these proved to be useless. Three alternatives as to the mode of election of the President were submitted to the Fellows—viz.: (1) election of the President by the Fellows, (2) nomination of the President by the Council and election by the Fellows, and (3) election of the President by the Council as now provided for by the Charters of the College. Of the 418 replies, 112 were in favour of election by the Fellows, 156 preferred nomination by the

Council and election by the Fellows, and 150 were satisfied with the present mode of election by the Council. Mr. HERBERT PAGE, who urged the Council at the meeting of the Fellows in July last to canvass the Fellows on the mode of election of the President and to abide by the decision whatever it might be, gave it as his opinion that the poll showed that the great body of Fellows did not desire any alteration in the present mode of election, and that no change ought to be made. It was pointed out, however, by Mr. RIVINGTON, and subsequently by Mr. VINCENT BELL of Rochester and Mr. HOLMES, that, so far as the poll went, it exhibited a considerable majority in favour of election of the President by the Fellows either directly or after previous nomination by the Council, and that if the canvass had been undertaken by the Council the majority would in all probability have been considerably larger. As the numbers at present stand it will be seen that of 418 Fellows 268 are in favour of the Fellows electing the President and 150 in favour of the present mode of election. This may be construed to show a substantial preponderance of opinion in favour of a modification in the present mode of election.

The main argument for the present method is that the Council have the best opportunities of judging of the fitness of their colleagues for the office of President; whilst the upholders of election of the President by the Fellows, aspiring as they do to share in the life of the College, regard the election of the President by the Fellows as a higher honour to the selected candidate than election by the 24 Fellows who constitute the Council. The middle course—nomination by the Council and election by the Fellows—would satisfy the legitimate aspirations of the Fellows and would obviate the objections of some that election directly by the Fellows might result in the elevation of a candidate not well qualified to preside at the Council and the College meetings, and to transact the business devolving upon the President.

At the conclusion of the discussion on the result of the canvass of the Fellows in reference to the mode of election of the President Mr. W. H. BENNETT, on behalf of the Society of Fellows, moved, and Mr. HOLMES, on behalf of the Association of Fellows, seconded, the following resolution: "That the Council be requested to appoint a conjoint committee of members of the Council and other Fellows of the College to consider the desirability of obtaining a new Charter together with the details thereof." The reasons given in favour of the resolution by the two speakers were curiously dissimilar. Mr. BENNETT spoke as if he rather courted a decision against the expediency of the Council applying for a new Charter at all; whilst Mr. HOLMES spoke as if there could be no question of the necessity for a new Charter for the advantage alike of the Council, the Fellows, and the Members of the College. Mr. BENNETT rejoices in the thought that the days of antagonism between any number of the Fellows and the Council are gone never to return, and is anxious for finality whatever the issue of the present application of the two societies may be. Mr. HOLMES disclaims the idea altogether that any antagonism has prevailed, and regards the formation of a joint committee of the Council, Fellows, and Members of the College

THE LANCET.]

THE BATTLE OF THE MEDICAL

is an announcement of an act of progressive action in the public and profession of the great corporation of which he is so worthy a member. It may be that in the deeper lines in which the resolution was presented the meeting had some effect upon the division, for 22 were in favour and 14 voted against it. This, however, is at once due to two, and whatever the answer of the Council for up it is plain that the fulfilment of the legitimate aspirations of the Fellows and of the Members of the College cannot be delayed for any lengthened time.

It is a question of the balance between honourable and humane motives in the fighting against the supporters of the abuse of the medical system proceeds. It is pitiable to see a great number driven to assert its rights in this fashion; but it is the lack of the profession. For a long time it has been the unwilling victim of its own willingness to befriend the one it has almost come to be believed that its aid is a not without terms and that others may be assisted in the same way. If it is undignified in a medical man to come for remuneration before answering a call to an emergency or case of disease, it is mean on the part of those who are likely to require his services not to treat him as he deserves, and in doing so to estimate justly his value. It may seem a light matter to ask a medical man to write a prescription, to visit a patient, to set a bone, or to see a woman safely out of the dangers of childbirth. Those who judge so do not think at all. They refer to the elements of character that go to make of a medical practitioner, or the years of study, or the innumerable individual cases and circumstances. The man of high calibre are the elite of the working classes. They are now what good medical attendance is and what it was. Many of them make the best private patients of the medical practitioners of a neighbourhood. If it were not for the medical man less than some of his richer neighbours they are not the less esteemed. This, after all, is the proper form of medical attendance for rich and poor. It is the better both for families and practitioners. Medical men in clinics, and still worse in medical aid associations, are a more or less treatment in the lump and in a way that ought to be restricted severely to classes to whom it is a real accommodation. The more it is so the better will it be for those who remain to be considered. To effect such restriction is the aim of the medical man of Cork at the present crisis, and in their efforts they would have the assistance and co-operation of every member of the medical profession. It is to be said that while there is unanimity in Cork in the medical men, strangers from without are ready to delegating several of the proceedings on Jan. 1st at a meeting of the St. Luke's Mutual Benefit Society. It is and it is to be said that a great deal of good feeling came out of the meeting of a letter to the secretary of the St. Luke's Mutual Benefit Society from its medical officer, Mr. G. L. L. L., intimating that unless the society's labours were to be able to do more for the medical profession, the society would have to be reformed, with great consideration.

as the commencement of an era of progressive usefulness to the public and profession of the great corporation of which he is so worthy a colon. It may be that the divergent lines on which the resolution was presented to the meeting had some effect upon the division, for 22 voted for it and 14 voted against it. This, however, is at least three to two, and whatever the answer of the Council may be, it is plain that the fulfilment of the legitimate aspirations of the Fellows and of the Members of the College cannot be delayed for any lengthened time.

THE contest in Cork between honourable and humane medical men fighting against the supporters of the abuse of the club system proceeds. It is pitiable to see a great profession driven to assert its rights in this fashion; but it is not the fault of the profession. For ages it has been the unrelenting victim of its own willingness to befriend the poor, till it has almost come to be believed that its aid can be had without terms and that others may be assisted in the same way. If it is undignified in a medical man to stipulate for remuneration before answering a call to an emergency or case of disease, it is mean on the part of those who are likely to require his services not to treat with him beforehand, and in doing so to estimate justly his claims. It may seem a light matter to ask a medical man to write a prescription, to visit a patient, to set a limb, or to see a woman safely out of the dangers of childbirth. Those who judge so do not think at all. They fail to remember the elements of character that go to make a good medical practitioner, or the years of study, or the thought for individual cases and circumstances. The members of clubs are the *élite* of the working classes. They know what good medical attendance is and what its value. Many of them make the best private patients of the best medical practitioners of a neighbourhood. If they pay the medical man less than some of his richer patients they are not the less esteemed. This, after all, is the proper form of medical attendance for rich and poor. The more of it the better both for families and practitioners. Treatment in clubs, and still worse in medical aid associations, is more or less treatment in the lump and in a crowd. This ought to be restricted severely to classes to whom it is a real accommodation. The more it is so restricted the better will it be for those who remain to be so attended. To effect such restriction is the aim of the medical men of Cork at the present crisis, and in their efforts they should have the assistance and coöperation of every member of the medical profession.

We regret to say that while there is unanimity in Cork among the medical men, strangers from without are ready to take the vacated places. The *Cork Constitution* gives an interesting account of the proceedings on Jan. 1st at a meeting of the St. Luke's Mutual Benefit Society. It is pleasant to be able to say that a great deal of good feeling and common sense characterised the proceedings, which began with the reading of a letter to the secretary of the St. Luke's Mutual Benefit Society from its medical officer, Mr. PHILIP G. LEE, intimating that unless the society accepted the new rules he would cease to act as their medical officer after Jan. 1st, but agreeing, with great consideration,

to act for a month in order that no member should suffer inconvenience. Nothing could be more satisfactory than the way in which the members spoke of their medical officer, whom they evidently appreciate. One of the members, Mr. HOSKINS, while denouncing the rules as infamous, declared he never knew a medical man for whom he had more regard than he had for their own. Strange that it should not strike Mr. HOSKINS that such a man would be the last to agree to "infamous rules." Sir JOHN SCOTT, in speaking, paid a high tribute to the medical men of Cork, and expressed himself in favour of seizing any chance of an amicable arrangement. Several speakers intimated that the medical men were willing to meet delegates from the club. In the end it was resolved unanimously to advertise for a medical officer, and the secretary was instructed to advertise in Dublin, Cork, and Belfast. But, as we have already said, there is a danger of the medical officers being supplanted by strangers. At this very meeting it was intimated by Mr. PRITCHARD that "there was a medical officer in the town now who was willing to do duty for that society or any other in town free for the present, and if he was not appointed he was willing to give up the society to any medical man that was appointed." Similar intimations were made in several other societies. At the Church of Ireland Young Men's Mutual Benefit Society a medical officer with numerous qualifications was unanimously elected. At St. Finn Barre's Mutual Benefit Society on the same day, Dr. MAGNER having resigned, it was resolved to advertise, the gentleman above referred to to take charge in the meantime. At a meeting of Joe Ronayne's Branch of the Irish National Foresters, in place of Dr. MAGNER, resigned, a medical gentleman, "late of London," was elected to the vacancy. We can only leave these gentlemen to their own reflections. They are acting within their legal rights, but it is acting disloyally to their profession and its best interests. It will never be a consolation to them to reflect that at a great crisis in the medical profession in Cork they took the wrong side. They cannot make an excuse either the hardship of the poor or the unreasonableness of their medical brethren. They are dissociating themselves from men who stand high in the opinion of their patients and who are fighting the true battle of the profession.

We cannot believe that the leaders of the clubs in Cork will think by such offers of temporary help that they are doing the best for the members. A medical man cannot be displaced by the first comer who offers himself. Good mechanics of tried service cannot be disposed of in that way by any good employer, and a medical man is much more than a mechanic. We are glad to learn that the medical men are willing to meet delegates of the clubs and are showing a conciliatory disposition. Any reasonable concessions should be made; but the main demands of the medical men are reasonable and should be pressed. The writer of a letter to the same issue of the *Cork Constitution* signing himself "Often Puzzled" maintains that the ordinary charges of Cork medical men are higher than those of English practitioners. He maintains that if fees are properly tabulated and regulated according to the means of the patient, estimated on rental, many will leave the clubs and become private patients. We fancy there can be little doubt

that in Ireland two causes have contributed to derange the proper relations of medical men to the public. One is the dispensary system, making it too easy to get attendance for nothing; the other is an ideal system, according to which every practitioner is to charge the traditional fee of one guinea per visit. There is room between these extremes for the mass of the people to be attended on terms neither impracticable to the patient nor unjust to the medical practitioner. The present crisis should end in the definition of such terms and strangers should withdraw.

LONDON has now for many years had to consider methods of collection and disposal of its house refuse, questions which have been full of difficulty since the time when this refuse had a distinct monetary value. In former times, when building operations were carried on in the metropolitan area to a much greater extent than they are now, contractors were willing to make terms with parish authorities for the privilege of collecting and disposing of refuse which are impossible under the altered conditions of the present day. In those days the manufacture of bricks gave ample opportunity for the utilisation of the "breeze," and in much greater degree than at present the "soft core" could be used for the fertilisation of the soil, and other components of the refuse could be turned to profitable account. As time went on, and the value of the refuse diminished, the contractors demanded larger and larger sums for its removal from houses, until sanitary authorities have been left to determine the question whether its destruction by fire is not the most economical procedure. The quantity of this material which has to be removed, and the manner in which it may best be burnt, may be learnt from a report issued in 1893 by the medical officer and engineer of the London County Council. This report was evidently prepared with the intention of putting the Council in a better position to insist on the more effectual scavenging of London. Contractors had in some instances become negligent; refuse, at periods when it could least be utilised, was left to create nuisance in houses, and sanitary authorities had only in some districts the enterprise to organise arrangements of their own, which made them independent of the contractor's natural desire for profit.

A report has just been issued by the County Council's medical officer which is a proper sequel to that to which we have referred. It contains a summary of reports by Dr. C. W. F. YOUNG, assistant medical officer of health, on the collection and disposal of refuse by London sanitary authorities. This summary contains much matter of considerable interest, and the London County Council have done a useful piece of work in making the results of their officer's inquiries generally available. Considering first the methods of disposal, the report points out that in twenty-five districts the sanitary authorities themselves collect the refuse without the employment of a contractor. In the case of six only of these authorities is the refuse subsequently manipulated in dust-yards in London—in all other cases it is either destroyed by fire or removed by barge or rail beyond the limits of the county. Evidently, therefore, sanitary authorities are not

disposed to enter upon the precarious business of endeavouring to turn the disposal of the refuse to profitable account in London. If it has any value in their hands, this can be as well or better secured by its immediate removal into country districts, and this is evidently the course which is suggested to any authority desiring to free London from the nuisance which attends the accumulation of large quantities of house refuse in its midst. The refuse of fourteen districts still employing contractors is manipulated in whole or in part at dustyards within the county. This may be due either to the better opportunities which the contractor possesses for the profitable utilisation of the refuse in London, perhaps in connexion with building operations; but it may also in part depend upon insufficient recognition of the disadvantages which attach to the existence of dustyards in a crowded city. It is probable that at no distant time the contractor will feel the weight of the by-laws of the London County Council relating to the carriage and disposal of offensive matter, and that the remaining yards in which house refuse is manipulated will gradually disappear from the metropolis. Dr. YOUNG's report shows that the employment of machinery is in these yards replacing the old system of hand sorting, and certainly no one familiar with the business of hand-screening carried on in the dustyards will regret this change. The spectacle of women standing up to their waists in dust, holding the sieves into which spadeful after spadeful of refuse is thrown is one which is not easily forgotten by the spectator. With the cleaner operations of machinery there has been more regard than formerly for the health and comfort of the workpeople. Waterclosets have generally been provided, and in particular instances, although only exceptionally, lavatory accommodation and rooms for meals.

The subject which most affects the comfort of the householder is the removal of refuse from his premises. Dr. YOUNG's report gives an account of the arrangements adopted in each district, and certainly on paper these arrangements in many districts do not appear open to objection. In the working, however, there is much to be desired. The claim made by sanitary authorities that dust is removed from every house once a week is often found in practice to mean that carts perambulate the street and the householder has the opportunity, if he hears the dustman's cry, to call him to his aid. To test the value of the scavengers' operations an inspector was employed by the Council to make a house-to-house inquiry, and the actual results were learnt by visits to some thousands of houses. Londoners, who know the difficulties they experience, will not be surprised that the Council's medical officer urges that the scavenger should call at every house at least once a week and that nothing short of such a system will effect the much-needed weekly removal of house refuse. We note with satisfaction that the publication of this report is not the only result of Dr. YOUNG's inquiries. The Council have already addressed themselves to sanitary authorities in cases where their administration needs amendment. They will no doubt persevere in the work which they have undertaken, and at no distant time it may be hoped that householders in London will find that their dustbins are emptied with as much regularity and certainty as the report demands.

ALMONERS.

THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE PRESIDENT OF THE GENERAL MEDICAL COUNCIL.

THOMAS WAKLEY, F.R.C.S. Eng.

THOMAS WAKLEY, Jun., L.R.C.P. Lond.

HON. AUDITOR.

SIR HENRY PITMAN, M.D. Camb., F.R.C.P.

—:O:—

THIS FUND will be provided year by year in the month of January to the amount of at least £300 solely by the Proprietors of THE LANCET, and administered free of cost, for the purpose of affording immediate pecuniary assistance to Medical Men, or their Widows and Orphans, *in cases of Distress and Emergency*, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require.

Applicants must satisfy the Almoners of the Fund that they are qualified under the following regulation:—

- * “The recipients shall be such persons as satisfy the Almoners that they possess one or other of the following qualifications—that is to say: (a) That the applicant holds a registered medical qualification, and that he has fallen into pressing need of immediate pecuniary relief; or (b) That they are persons who have been, previously to the date of application, legitimately dependent upon some person holding a registered medical qualification, and that they have pressing need of immediate pecuniary relief.”

To ensure the utmost despatch, the “Application Form” upon the other side should be filled up and forwarded (in an envelope superscribed “THE LANCET Relief Fund”) to the Secretary, Mr. EDWARD DAVIES, THE LANCET Offices, Strand, London, W.C.

The application should be accompanied by two separate testimonials, one from the Clergyman of the Parish or other resident Minister of religion, and one from a registered Medical Practitioner, stating—that the application addressed to the Almoners has been read, how long they have known the applicant, and that they believe the statement to be perfectly truthful, and such as may be acted upon without further inquiry.

Private and Confidential.

No.

APPLICATION FORM.

To the Almoners of the Lancet Relief Fund.

The applicant should here state shortly :—

1. The nature of the emergency that has arisen.

—

—

2. The circumstances out of which it has arisen.

—

—

3. The amount of the grant desired, and whether by way of loan (free of interest) or of gift.

—

—

—

4. If by way of loan, state when the loan will be repaid; and from what source the funds to repay it are expected to be forthcoming.

—

—

—

1. Whether the applicant is entitled or able in the circumstances to receive the grant; and if so, what is the expected nature and extent of the emergency.

2. Whether the applicant is receiving, or has received, any other assistance from any source.

3. State how the applicant is qualified to receive the grant.

4. Particulars of:

Applicant's age

Number in family

How many are self-supporting

How many are partially dependent

How many wholly dependent

Applicant's Signature

Address

Date

5. Whether the applicant is entitled or able in the circumstances which have arisen to look to any other source assistance ; and if so, what is the expected nature and extent of such assistance.

6. Whether the applicant is receiving, or has received during the past six months, pecuniary aid from any Medical Charity.

7. State how the applicant is qualified to receive assistance ; vide regulation* on first page.

8. Particulars of :

Applicant's age

Number in family

How many are self-supporting

How many are partially dependent

How many wholly dependent

"Ne quid nimis."

THE REGIUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF OXFORD.

To most the appointment of Professor Burdon Sanderson, F.R.S., as Regius Professor of Medicine in the University of Oxford will come as a foregone conclusion. His scientific record is not only unparalleled among medical men, but would be hard to parallel in spheres of wider rivalry, while he possesses to an eminent degree the qualities that most aptly pertain to the University professor. Professor Burdon Sanderson's public work has been of the most valuable sort. He has been employed by the Government to make investigations upon such different subjects as cattle plague, cerebro spinal meningitis, and the influence of heat on the health of miners; and twelve years ago he sat on the Royal Commission on Hospitals for Infectious Diseases, and quite recently on that appointed to inquire into the question of a Teaching University for London. But it is as a physiologist that he makes his recognised claim to celebrity, and we may be excused to medical readers from detailing his well-known work. It is as a physiologist also that he has been elected to the new post, and in this sense the appointment is a departure. But it is a departure that can be thoroughly well justified, for by as much as it is the boast of the followers of modern medicine that their practice is founded upon and developed from scientific principles, by so much must the tried worker in pure physiology be the fit person to become the great exponent of practical medicine. We congratulate Professor Burdon Sanderson upon his appointment, laying stress upon the fact that it comes very distinctly as a reward of merit, seeing that he has already served fourteen years as an Oxford professor of less exalted degree; and we congratulate the University upon securing for what is naturally in our eyes one of the most important professorial chairs, a man who is able to fill it.

THE SUPPORT OF HOSPITALS.

CONSIDERABLE attention has been drawn to the unsatisfactory state of the finances of Charing-cross Hospital, and a cursory glance at the seventy-third annual report shows that the debt of the hospital has increased during the preceding twelve months from £5394 1s. 7d. to £11,392 5s. 7d. The governors, in face of this alarming fact, as may be imagined, have been compelled to announce that the time was rapidly approaching when the hospital should not be allowed to exist on the generosity of its bankers. The cost and method of administration of the charity do not explain this serious depreciation, but legacies show the huge deficit of £6000 as compared with the previous year. The general financial depression adds greatly to the embarrassment which Charing-cross Hospital so severely feels, while the new scale of death duties can hardly fail to adversely affect in the future the revenue of all charities; for when a man of means has to provide for the loss of a large sum at his death his charitable subscriptions are usually the first to cease. We use Charing-cross Hospital as a text, but it is well known that many other institutions are in a similar pecuniary plight. The general and colossal apathy of the vast bulk of the public concerning the support of hospitals is due in part to ignorance and in part to the enormous amount of work of national importance done unostentatiously and gratuitously by the medical profession. When we reflect that a hospital, with a medical school attached, is not only a place where disease and suffering are cured and

alleviated, but where disease is studied and knowledge of it improved, where medical men are educated for the good of the nation at large, we can easily see of what vast importance to the nation these institutions are. It has recently been pointed out in our columns that the medical and surgical teachers at the London hospitals alone, by their practically gratuitous work in educating students, present something like £200,000 to an opulent nation annually; but how few of the public know or think about these things? The patient who blesses his medical attendant for saving his life little reflects that his skill was acquired in the wards of a hospital possibly on the point of closing for want of funds. In short, the financial condition, not of Charing-cross Hospital only, but of many other similar institutions, might readily serve as a text to open up the very large subjects—subjects growing in urgency and soon to burst into unrestrainable prominence—the support of our teaching hospitals and the *raison d'être* of so much gratuitous medical work. Charing-cross Hospital is not large, and its beds are comparatively few. The useful work it does is undeniable, and its medical school performs excellent service in the training and education both of medical men and of dental practitioners. It would be little short of a disgrace to the richest city in the world if such an institution had to close its wards for want of funds.

DEATHS IN LAUNDRIES.

THE appalling loss of life through the fire at a French laundry establishment in the Edgware-road afforded both the coroner and the jury who held an inquest on the bodies of the eight victims at Marylebone an opportunity of urging that laundries should be brought under the operation of the Factory Act. It was only the other day that a man died in consequence of an accident and of the weakness resulting from overwork in a Battersea laundry. The coroner's inquest held on that occasion revealed a state of things which, as we remarked at the time, would not have existed had the Factory Act applied to laundries. Now, in the Marylebone district we find a very extensive laundry business carried on in two private houses, 412 and 414, Edgware-road. Between forty and fifty persons were employed on the premises. Surely this was to all intents and purposes, if not a factory, at least a workshop, and as such should have been rigorously inspected. The mistress of the laundry and seven assistants slept on the establishment. These eight persons lost their lives in the fire. It appears that they were in the habit of retiring to rest in the upper part of the house, while below linen was hung out to dry in rooms where four stoves were left burning. That the linen might fall on these stoves and ignite was evidently foreseen, as, with one exception, there was a wire protection over the stoves. Perhaps the one unprotected stove was the cause of the fire; in any case, had the laundry been under the Factory Act more effective precautions would doubtless have been enforced by the factory inspector. At the inquest the coroner, Dr. G. Danford Thomas, said he had held an inquest at Islington only the previous day upon a man who had been decapitated at a steam laundry; and Mr. Cameron, one of Her Majesty's inspectors of factories, who then watched the proceedings on behalf of the Home Office, said that he thought it very desirable that laundries should be included in the Factory Act. In this opinion the coroner thoroughly concurred. The Marylebone jury in their verdict on the Edgware-road fire stated that they were of opinion, and recommended that all laundries should be placed under the provisions of the Factory Act. It has been urged that only laundries where steam power and machinery are employed should be included in the Factory Act. We are glad to note that the jury in their

recommendation wished to see the Act enforced in all laundries. Though forty or more people were employed at the Edgware-road laundry, it appears that there was no machinery, and consequently such establishment would escape inspection if all laundries are not subjected to the proposed extension of the Factory Act. From the above it will be seen that within a month coroners' inquests have been held with respect to the loss of human life in three different London laundries. This is evidence of a sufficiently startling and dramatic character to enforce our contention that laundries must be brought under the Factory Act. Yet this is nothing as compared to the enormous loss of human life which is brought about slowly, without any attending dramatic circumstances and publicity, through the life-wasting, insanitary conditions under which much of the laundry work is done.

CLUB TOWELS.

It is the general practice in the better-class clubs to provide an unlimited supply of towels. Each time a member washes his hands he uses a clean towel. As a rule, in wiping his hands once the towel is barely, if at all, soiled. It cannot be expected that under these circumstances the towel will be properly washed. There is nothing to wash. It suffices to dip the towel in some water, to dry and iron or mangle it, and to all appearances it is again fit for use. Would such a perfunctory performance suffice to cleanse a towel? Indeed, it raises the suggestion whether towels used in restaurants, clubs, &c., should not be disinfected as well as washed. Of course we presume that no one would knowingly go to a club while suffering from an infectious disease; but it sometimes happens that a person is in an infectious condition without being aware of the fact. Moreover, infection of towels may occur, and it would be much more satisfactory to know that they were thoroughly disinfected as well as scalded and scrubbed. Boiling water may be considered an excellent disinfectant. If in the light of modern bacteriology the immersion of linen in boiling water during the process of washing may not always be of sufficient duration to destroy every known germ, the boiling of linen nevertheless does afford a certain degree of protection against the seeds of disease; but the towels of high class clubs are generally so clean when sent to the laundry that they are apt to receive less than the usual amount of scrubbing and boiling. There is a virtue after all in dirt if it ensures a thorough cleansing, and a really dirty towel is likely to be more thoroughly washed and cleansed than a comparatively clean one.

RESPONSIBILITY OF DISTRICT SURVEYORS.

SOME correspondence which has recently passed between Mr. J. Galloway Weir, M.P., on the one side, and the Home Secretary and the President of the Local Government Board, on the other side, goes to show that the district surveyor is in the enviable position—or unenviable, as the case may be—of exercising a jurisdiction from which there is no appeal. To suggest that the control of an appellate court may be an advantage to the authority controlled may at first sight seem to savour of affectation. But a little reflection will show that district surveyors are in a position to be very specially exposed to the attack of improper influences if they are understood to be the depositories of an uncontrolled power. To an upright man nothing is more disagreeable than to have to be constantly repelling improper advances; but that is probably the penalty of such greatness as we have referred to. The sooner, therefore, that an official superior can be found for the district surveyor the better it will be both for him and for the public. Mr. Weir, whose complaint had reference to the deconstruction of some houses in London, addressed first of all to the London County Council, but

his remonstrances led only to a disclaimer on the part of that body of any responsibility for the acts or omissions of the district surveyor. Their correspondent, appealing next to the Home Office, was informed that the Home Secretary had no jurisdiction; and we see from a notice of this correspondence in the pages of our evening contemporary, the *Pall Mall Gazette*, that the Local Government Board is said to have taken a similar attitude. It may be, of course, that Mr. Weir has not yet applied in the right quarter for redress; but, at least, he has given himself no small amount of trouble, and it cannot be doubted that the machinery—which, with all his industry, he has failed to set in motion—is useless for practical purposes. When it is considered how important are the duties which district surveyors undertake, how large the confidence which Parliament and the public repose in their integrity and energy, and how insidious and far-reaching the consequences of their misconduct or mere neglect may be it becomes at once evident that some more effective discipline than is at present available is required for the perfecting that branch of the public service which it is their province to administer. If further legislation be necessary let us have it, and the sooner the better; but in the meanwhile cannot some one of the departments which have satisfied themselves that they do not possess the jurisdiction inform us to whom to go?

KITCHEN BOILER EXPLOSIONS.

IN spite of the occurrence of several catastrophes which were due to the sharp visitation of frost just exactly a year ago there have been no practical official investigations since made into the causes of kitchen boiler explosions, and there will be little reason for surprise, therefore, if any increase in the severity of the weather which we are experiencing at the present time should result in a similar series of disasters. The urgent necessity of amending the Boiler Explosions Act of 1881, so as to bring within its operations the explosions of kitchen boilers, is especially evident when regard is had to the fact that the number of fatalities and cases of personal injury due to such occurrences exceeded considerably the number of those accounted for by all the explosions of ordinary steam boilers throughout the United Kingdom during 1893. There is now no reason why legislation should not be brought to bear immediately upon the management of domestic hot-water appliances, since there is no longer any obscurity surrounding the cause of these explosions. On this point there was a large diversity of opinion, and in the interests of the public safety we ourselves gave some attention to the subject and expressed our views in the columns of *THE LANCET*.¹ Although we freely admit that these views were based in a measure on theoretical considerations, yet it was a source of considerable satisfaction to us to learn, as we have since learned, that the publication of these opinions led to a complete ventilation of the subject in the lay and technical press; but even in the ideas expressed in the latter, we should observe, there was by no means an absolute accordance of opinion. Speculation has at length yielded to the teaching of practical observation in the results of a very interesting and conclusive series of experiments carried out under the evidently able instructions of Mr. R. D. Munro, M.I.M.E., the chief engineer to the Scottish Boiler Insurance and Engine Inspection Company, Limited, Glasgow and Manchester. The highly instructive and practical results of this really important investigation are embodied in a *brochure*, a copy of which has recently reached us.² Mr. Munro's tests were eminently practical³

¹ THE LANCET, Jan. 13th, 1894.

² Kitchen Boiler Explosions: Why they Occur and How to Prevent their Occurrence. By R. D. Munro, M.I.M.E. London: Charles Griffin and Co., Limited, Exeter-street, Strand. 1895.

and every conceivable and possible cause of kitchen boiler explosions was investigated. Briefly, his conclusions are drawn from the fact that the explosion of a domestic boiler is not a mystery about the explosion of a domestic boiler, but that the theory which creates an unknown and highly explosive gas for this purpose is absurd, and that it is equally erroneous to believe that these boilers burst suddenly by the sudden generation of steam consequent upon water being introduced when they are red-hot. Domestic boilers cannot burst disastrously unless they contain a store of highly heated water immediately prior to a rupture occurring, and the damage which they are capable of causing is in proportion to the quantity of hot water. In this respect they resemble ordinary steam-boilers, and their safety can only be secured by being so equipped and treated as such. As to prevention, we maintain "a safety valve is the simplest and most efficient preventive of over-pressure, and if properly constructed and placed it is less liable to stoppage than any other pressure-reducing or relieving device." The valve should be arranged so as to be free from rust and dirt and also quite accessible for examination. It may be placed in a small room at the back of the fireplace. We strongly recommend that the notice of householders. It is simply and clearly written and contains not a single paragraph which will not be read with profit and instruction. As it has been expressed in the disease is now understood and remedy has been found, and it only remains, we may add, to apply the wisdom in the suggestion, which should be presented to the Board of Trade, that just as boiler-makers are made to incur a responsibility under the Boiler Explosions Act, so hot-water engineers should be made responsible when they fail to fit up boilers and their contents in a safe and efficient manner. We trust this notice will receive the serious consideration which it merits.

SERO-THERAPY AND SANITATION.

In the result of a tour through the great cities of England and Scotland Dr. Angelo Celli, Professor of Hygiene in the University of Rome, put on record his opinion that in all cases of sanitary regulation and hospital equipment Italy will have behind the British Isles. The fact is admitted that the Italian Hygienist's companions, and that we are not far to seek. One of them is the necessity of the slow, prosaic methods of sanitary precaution and a belief, almost medieval, in the power of drugs. This superstitious reliance on "pharmaceutical" to health accounts for the fact that even the most experienced agents in the pharmacopoeia have been found to be defective in public hospital or private practice. So defective are these in the elementary control of useful life—viz., prompt and thorough removal of the pure water supply, and fresh air. The recent introduction of the modern treatment of diphtheria illustrates this point. In Italy—and, indeed, to a large extent in France—methods of combating disease. While in Great Britain, as applied to diphtheria, is still the case of careful induction and cautious application to the cases of the "sovereign remedy" or "specific" which with its "antitoxin" is hailed. Let the case dip into any lay journal south of the Alps, and you will find towns and cities and communes, hitherto regarded, mischievously large sums to send young physicians and health officers to Paris or Berlin to study the science of sero-therapy, and to bring home plentiful supplies of serum for immediate use. Populous centres, still, are to take their drinking water from wells sunk in

and every conceivable and possible cause of kitchen boiler explosions was investigated. Briefly, his conclusions are that there is no mystery about the explosion of a domestic heating boiler, that the theory which creates an unknown and highly explosive gas for this purpose is absurd, and that it is equally erroneous to believe that these boilers burst *disastrously* by the sudden generation of steam consequent upon cold water being introduced when they are red-hot. Domestic boilers cannot burst disastrously unless they contain a store of highly heated water immediately prior to rupture occurring, and the damage which they are capable of causing is in proportion to the quantity and heat of the water. In this respect they resemble ordinary steam boilers, and their safety can only be secured when they are equipped and treated as such. As to preventive measures, "a safety valve is the simplest and most effectual preventive of over-pressure, and if properly constructed and placed it is less liable to stoppage than any other provision yet suggested or applied." The valve should be so situated as to be free from soot and dust and also quite accessible for examination. It may be placed in a small case set into the back of the fireplace. We strongly recommend this little book to the notice of householders. It is sensibly and clearly written and contains not a single paragraph which will not bared with profit and instruction. As Mr. Munro expresses it, the disease is now understood and the remedy has been found, and it only remains, we may add, to apply it. There is wisdom in the suggestion, which should be represented to the Board of Trade, that just as boiler-makers are made to incur a responsibility under the Boiler Explosions Act, so hot-water engineers should be made liable to penalties when they fail to fit up boilers and their connexions in a safe and efficient manner. We trust this matter will receive the serious consideration which it demands.

SERO-THERAPY AND SANITATION.

As the result of a tour through the great cities of England and Scotland Dr. Angelo Celli, Professor of Hygiene in the University of Rome, puts on record his opinion that in all aspects of sanitary regulation and hospital equipment Italy is 200 years behind the British Isles. The fact is admitted by others of the Italian hygienist's compatriots, and its causes are not far to seek. One of them is undoubtedly an impatience of the slow, prosaic methods of sanitary precaution and a belief, almost mediæval, in the power of drugs. This superstitious reliance on "royal roads" to health accounts for the fact that even the most unquestioned agents in the pharmacopœia have not a fair chance in Italy, whether in public hospital or private dwelling, so defective are these in the elementary conditions of healthful life—viz., prompt and thorough removal of refuse, pure water-supply, and fresh air. The recent introduction of the antitoxin treatment of diphtheria illustrates this weak side in Italian—and, indeed, to a large extent in Continental—methods of combating disease. While in Great Britain sero-therapy, as applied to diphtheria, is still the subject of careful induction and cautious application to practice, in Italy and other European States it has been welcomed at once as a "sovereign remedy" or "specific," and the causes of the "bane" itself are forgotten in the enthusiasm with which its "antidote" is hailed. Let the reader dip into any lay journal south of the Alps, and he will find towns and cities and communes, hitherto so poor as to leave their drainage and water-supply neglected, subscribing large sums to send young physicians and health officers to Paris or Berlin to study the *rationale* of sero-therapy, and to bring home plentiful supplies of the serum for immediate use. Populous centres, still content to take their drinking water from wells sunk in

the subsoil or to let their sewage stagnate in antiquated drains *en route* to the stream that flows past them, grudge no expense in procuring the "anti-diphtheritic elixir," as it has been called. The same readiness to lose sight of prevention in the eager hunt for cure has, indeed, been witnessed abroad in other diseases besides diphtheria—the discovery of this or that "bacillus" and its putative counter-agent being quite enough to arrest or discourage every effort to check the malady in question at its source. We have in all this an example of the slow progress made by rational medicine in countries that have not yet cast the slough of mediæval tradition—an imperfect realisation of the etiology of disease; a practical ignorance of medicine as a branch of nature study; a hugging of the chains of scholastic "system" in forgetfulness of the lines on which the healing art was laid by the Father of Medicine himself. Sero-therapy has, doubtless, a great future before it, and in other maladies besides diphtheria, but its introduction would be a doubtful blessing if, as in Southern Europe, it caused a neglect of the rudimentary conditions of health summed up 3000 years ago in the Hippocratic *περὶ ἀέρος, ὕδατος, τόπων* (concerning air, water, locality).

THE WANT OF SANITARY ACCOMMODATION IN LIVERPOOL-STREET.

THE planting of two great terminal stations in what was a generation ago the out-of-the-way thoroughfare of Liverpool-street has necessitated great alterations in the condition of that highway and its purlieus, but upon the whole less perhaps than might have been supposed by an old stager who could have foreseen the enormous development of the traffic which was destined to ensue. In one respect, however, he would not have been at all likely to over-estimate the consequences, for he could hardly have guessed that the omnibus traffic would expand to larger proportions than it has in fact assumed. Now, where the traffic brings omnibuses to a halting-place in even a small fraction of the numbers which all day long throng the roadway in front of the Broad-street Station, it is the obvious duty of the local ædiles to provide convenient sanitary accommodation for the 'bus men. That this duty should have remained unperformed to the present day is greatly to the discredit of somebody, and we hope that the responsibility is sufficiently clear to make the somebody in fault uncomfortable in his present neglect. He, or rather they, can hardly plead ignorance in a matter which forces itself so violently and so unpleasantly upon public attention. What excuse is there which can be put forward to palliate this manifest dereliction of duty?

"DENTISTS AND THE PUBLIC."

MUCH as we deprecate the general discussion of questions pertaining to the medical profession in the lay press, we have no hesitation in drawing attention to a pamphlet entitled "Dentists and the Public," a reprint of articles which recently appeared in the *Pull Mall Gazette*. In a sober and practical manner the writer deals with a profession in which, he says, charlatans unfortunately flourish, and advises those seeking aid and not knowing a reliable man to choose one who puts L.D.S., the only dental degree granted in this country, after his name. The Dentists Act, which was passed in 1878, was an attempt to clear an honourable profession from the evils with which it was beset. Up to that time there were a little over 2000 *bonâ-fide* dentists in practice, though few possessed degrees; but after the passing of the Act, which was made retrospective, no less than 480 persons, including chemists and their assistants, barbers, blacksmiths, &c., declared themselves to have been in *bonâ-fide* practice and therefore claimed the right to be on the Register. There are now 1306 registered dentists

who have taken the L.D.S. Of the 4806 who were admitted to the Register by virtue of their being in *bond-fide* practice before the passing of the Act 3489 still remain without any additional qualification. "Covering" is a serious evil and the writer urges that the time is ripe for strong legislative measures in regard to this matter. "American Dentistry," a phrase which has even less significance than "French polish" or "Russian leather," really means, as the writer points out, "Advertising Dentist," and we heartily agree with his closing words: "It cannot be too frequently reiterated that the man who advertises thereby stamps himself as unqualified. The properly qualified dental surgeon is under obligations exactly similar to those of the medical man with respect to advertising."

THE PURIFICATION OF WATER FOR DOMESTIC USE: A SUGGESTION.

SINCE bacteriology was born there has always existed a doubt as to whether the majority of domestic filters could render water free from bacteria or could reduce their number to any practically valuable extent. From time to time bacteriological investigations have been made with a view to set these doubts at rest, and on the whole the results have fully realised these anticipations. Still more complete and thorough probably than any work previously done in this direction is that recently published by Drs. Sims Woodhead and Wood,¹ who, as a result of their experiments, exempt very few domestic filters they have examined from the charge of inefficiency to remove organisms. Results like these, of course, must shake to its very foundation the confidence which the public has hitherto reposed in domestic methods of filtration, and the cry naturally follows, On what method, then, may we rely? As is the case with so many departments of study, in centring our attention on one method we have turned our backs on another, which, however, may possibly be equally good, if, indeed, not better. We have learned some striking lessons in late years of how nature effects the abundant purification of water; but it seems to us that we have imitated on the small scale only one of these processes—namely, the percolation of water through great depths of porous strata by which bacteria originally present are entirely removed. We have overlooked, we think, the equally important, because equally effective, natural process of purification by subsidence of particles during storage; and yet the irreproachable water of Loch Katrine, supplied to Glasgow, as well as the water supplied to most towns in the north of England, is submitted to no purification beyond the storage in reservoirs of vast size. Professor Percy Frankland showed over eight years ago that, if a water containing bacteria is shaken up with finely divided solid particles and allowed to subside for several hours, the large solid particles in falling to the bottom carry with them an astonishingly large proportion of the bacteria. Thus, after agitation with chalk for fifteen minutes of a water containing originally 8000 micro-organisms per cubic centimetre it contained only 270 organisms—a reduction equal to 97 per cent. Coke powder gave even a better result, for in a water containing innumerable organisms before treatment there were found absolutely none at all after subsidence of the coke particles, the reduction effected being therefore equal to 100 per cent. Similarly, animal charcoal effected a reduction of 99 per cent., the original water containing 8000 and after subsidence only sixty organisms per cubic centimetre. Vegetable charcoal, again, reduced the number from 3000 to 120, which is equal to a reduction of 96 per cent. There are strong reasons for believing, then, that, by the simple expedient of agitating water—say, with well-burnt powdered coke—and drawing off the water after

the particles have subsided, it would be freed from its organised and, it may be, its disease-producing inhabitants. This process appears certainly to be as simple as filtration and should give very little trouble in its practical working; moreover, it cannot surely be costly. Coke, unless well burnt, would probably impart a foreign taste to the water, which, however, could be removed by passing the water through a filter containing an oxidising medium, in which case the filter need not be an efficient remover of organisms, since after the subsidence treatment there should be none to remove. Confronted with these facts, we fail to see why this method should not be tried in the place of established methods of purification, which in the light of recent research have been shown to fail. We cannot imagine that it offers much inconvenience, trouble, or expense, while the water so purified would possess many obvious advantages over water that has been boiled. It could be easily adopted in hotels, schools, barracks, and other large buildings. We commend the attention of inventors to this apparently effectual, though simple, means of purifying water for domestic use.

HONOURS AT THE LONDON UNIVERSITY.

THE published list of the results of the recent examinations at the University of London shows a series of remarkable successes for St. Thomas's Hospital Medical School. In the Final M.B. Examination Mr. A. E. Russel obtained the gold medal in Medicine and Mr. C. S. Wallace the gold medal in Obstetric Medicine. In the B.S. Examination Mr. J. H. Fisher, F.R.C.S., took the scholarship and gold medal; Mr. C. S. Wallace, F.R.C.S., qualified for the gold medal; and Mr. S. W. F. Richardson, F.R.C.S., obtained first-class honours. In the M.D. Examination Mr. Seymour G. Toller took the gold medal; Dr. Toller had previously distinguished himself in the M.B. examination, 1892, when he took the scholarship and gold medal for Medicine and also for Obstetric Medicine.

CHARGE OF INDECENT ASSAULT.

AT the Oxford Sessions on Jan. 1st Mr. Samuel Daniel Hine, surgeon, was tried for having indecently assaulted Edith Hutchings, aged thirteen, on Aug. 14th last. From the evidence it appears that Mrs. Hine was away from home, and that Mr. Hine, who had previously employed the prosecutrix in a similar capacity, asked her to get his breakfast. The allegation against the accused was that he went into the kitchen, kissed the girl, and, under the pretence of auscultating her chest, passed the bounds of professional conduct. On the same day the girl complained to her mother and a neighbour. Mr. Hine's account was that, as she was troubled with a chronic cough, for which he had treated her, and as she did not look well, he examined her chest with a stethoscope, and as the girl complained of a pain in her stomach he placed his hand in that region to ascertain what was the matter with her. From some cause or other the prosecutrix cried, whereupon the defendant kissed her. On the one hand, it was contended that she cried in consequence of having been indecently assaulted, whilst Mr. Hine stated that he thought it was because he had hurt her by the pressure of the stethoscope. It was contended that prior to the alleged assault Mr. Hine locked the front door, but this was explained by the fact that the catch did not act properly. For the defence evidence was given that the mother of the prosecutrix had spoken of getting money out of Mr. Hine. The chairman of the sessions, in directing the jury, said how easy it was to make such charges and how difficult to disprove them, especially in the case of a medical man. The jury at once acquitted Mr. Hine. We fully endorse the chairman's charge and the verdict of the jury.

¹ Brit. Med. Jour., Nov. 10th, 1894.

A conviction could not be rightly obtained on the evidence, which tended to show animus on the part of the girl's mother, on the one hand, and, on the other, that of the prosecutrix was clearly open to the interpretation given by Mr. Hine. At the same time, we must confess that Mr. Hine acted very imprudently in making the examination he admitted having done under the circumstances in which he and the prosecutrix were placed. There was clearly nothing urgent in the case, and a wise discretion would have dictated to Mr. Hine to ask the girl's mother or some other person to be present.

THE DEATH OF LADY PAGET.

It is with deep regret that we chronicle the death of Lady Paget, the wife of Sir James Paget, a regret that we know will be shared by the whole of our profession, British and Colonial, English-speaking and foreign. Lady Paget was a daughter of the Rev. Henry North, domestic chaplain to Her Majesty the Queen's father, the late Duke of Kent, and was married to Sir James Paget as far back as 1844, their golden wedding being celebrated last year. We tender our sincere and respectful sympathy to Sir James Paget in the irreparable loss that he has sustained in this severance of a long partnership in affection.

THE PRESIDENCY OF THE INDIA OFFICE MEDICAL BOARD.

We announced last week that the Secretary of State for India had appointed Brigade-Surgeon-Lieutenant-Colonel W. R. Hooper, of the Indian Medical Department, to be President of the Medical Board at the India Office, in succession to Sir Joseph Fayrer, K.C.S.I. Brigade-Surgeon-Lieutenant-Colonel Hooper has held several important appointments in India, the last one being that of civil surgeon at Lucknow; and when he was in this country he acted, we believe, as a member of the India Medical Board and of the Army Medical Board. He has had a long and intimate as well as varied acquaintance with professional work in India. His experience as civil surgeon of different stations in that country has necessarily afforded him excellent opportunities for acquiring a practical knowledge of its diseases, and he is a deservedly popular member of the Indian medical service.

NURSES AND SMALL-POX DISSEMINATION.

DR. MONTGOMERY WARD, in presenting his last monthly report as superintendent medical officer of health to the Rathmines commissioners, Dublin, has expressed his conviction that one potent factor in the spread of small-pox and other infectious diseases is the action of nursing sisters from the various nursing institutions. He complains of their indiscriminate mixing with the healthy in the course of their attendance on patients suffering from disease of an infectious nature, as by travelling in public conveyances, frequenting public thoroughfares, places of worship and of amusement, and the like. He strongly recommends that the management of these institutions be asked to frame rules against this sort of thing, while also enacting adequate disinfection of the clothing of the nurses under the supervision of the sanitary authority. This advice is admirable; but is the risk to the public really great? Why not also enforce the wearing of some "infection-proof" dress by the nurses whilst engaged with the sick, one that can be easily disinfected before proceeding to another house, by whatever means of transit? Then such ablutionary exercises as can be secured would no doubt be valuable. With these precautions we fail to see what can be said against the kindly work of these sisters. It will, of course, always be well to keep nurses of one class of disease from attending patients suffering from one of a different nature; but whatever may be

the proof of the spread of disease in this way in the past—and we should deem proof as exceedingly difficult to obtain—there would appear to be a balance of considerations in favour of the use of trained nurses, for those persons who have unfortunately not been removed to hospital, over the indiscriminate going to and fro of ignorant even though kindly disposed neighbours. Indeed, the visiting of the sick by the healthy, except in case of great emergency, is to be deplored, since this has undoubtedly proved in only too many instances a sure method of spreading infection, and has not infrequently filled the hearts of health officers with despair when attempting to stay the spread of disease.

THE INCREASE OF THE PROFESSION.

THE first definite—though not official—information we get in the course of the year in reference to the numbers of the profession is contained in the admirable Medical Directory (Messrs. J. & A. Churchill) which also contains much other useful information. There is still insufficient indication of any adequate abatement in the tendency to overcrowd the profession which has been so apparent of late years and has been undoubtedly injurious to the tone and quality of medical practice. The numbers of the profession as they appear in the Directory for 1895 are 32,590, as against 31,772 in 1894 and 30,759 in 1893. In other words, there was an increase of 818 in 1895 over the previous year, as against an increase of 1013 in 1893 over the numbers in 1892. The 32,590 are thus distributed—we place the numbers of the previous year for comparison between parentheses. In London, 5742 (5590); in the provinces, 15,313 (14,897); in Scotland, 3224 (3107); in Ireland, 2511 (2485); resident abroad, 3321 (3209); the Services, naval, military, and Indian medical, 2452 (2426); too-late list, 27 (58). It is possible that we are about to see a reduction in the number of aspirants to medicine, which, considering the exaction of examining boards and the slight pecuniary rewards which follow, it is remarkable we have not seen sooner.

LONDON FIRES: PREVENTION THE BEST REMEDY.

It is a bitter thing that we have still much to learn from a teacher so unsparing as experience. We are ever ready to class his lessons among our misfortunes. Yet, after all, there is no one who will deny that in an important sense even these deserve our gratitude if, as it ought, reform follows upon their frequent exposures of our faults. Systems, companies, men are at one in this matter. There is no disaster which does not point the finger of blame at someone. Not even the unexplained catastrophe which occurred last week in Edgware-road constitutes an exception. It is true that the fire was accidental, that its precise cause is unknown, that all concerned in its extinction appear to have acted with admirable promptitude in the use of such means as were available, and that perhaps no system or method could have completely triumphed against the difficulties to be combated. Certain incidents connected with it, however, can only be remembered with regret. The fire is believed to have arisen in the drying-room of the laundry, probably from some clothes being hung up over a hot and unprotected stove—a circumstance which assuredly as we elsewhere point out suggests the wisdom, of extending the practice of official inspection to this class of establishments. Another and a far more important matter, however, was touched upon in the coroner's inquiry into this occurrence. This was the question of water-supply available in the metropolis in cases of like emergency, and the most effective means of its employment. In the case quoted fire-engines alone were used, and these after a brief but inevitable interval. This fact is somewhat painfully instructive not only when we consider

the actual loss of life incurred, but also when we reflect that some of our larger cities are able, thanks to a water-supply of constant and high pressure, to affix upon street hydrants suitably placed, hose which can at once and effectually control the beginning of a possible conflagration. To obtain such a supply for London would entail a very great and even a disproportionate outlay. Its realisation, therefore, however desirable, cannot for some time to come be counted on, unless, indeed, a proposed alternative method be adopted. This, which has already been applied in certain cases, as for the protection of New Scotland Yard and the National Gallery, consists in utilising by a combination hydrant the water-power of the Hydraulic Company to supplement that in our ordinary mains. The service available from this source is as yet of limited extension, but it includes in its area such districts as the City, Strand, and the docks. It is in these parts that widely destructive fires are most frequent, and in these, therefore, such a system as we have suggested should prove of the greatest advantage to persons and property. The suggestion is not a novel one. It has already been considered, and for the time being shelved, by the County Council. We should, nevertheless, like to hear more of it, or to learn by what other method it is proposed to endow a city abundantly supplied with water with the means of obtaining such continuous and high pressure in mains as shall render street hydrants in London, as in Liverpool, Glasgow, or even Hull, a general and an immediate means of fire extinction.

THE TENURE OF THE APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

WE learn that the Nottingham Medico-Chirurgical Society has recently had under consideration circumstances connected with the appointment of the medical officer of health of Ilkeston. This appointment had been held for ten years by Dr. Carroll, during seven of which he received £30 per annum, during two years and a half £50, and for the last six months at the rate of £75 per annum. The Ilkeston town council were, therefore, evidently beginning to appreciate Dr. Carroll's work, and were by degrees attaching a better salary to his office; but at the period when he should have been re-elected it is stated that he was informed that his ideas as a sanitarian were too advanced for a place of such modest dimensions as Ilkeston, and another medical man was selected in his stead at a salary of £100, this gentleman being, we are informed, himself a town councillor previously to his election. The society has therefore passed a suitable resolution and communicated it to the local Members of Parliament, to the Parliamentary Secretary of the Local Government Board, and to the Incorporated Society of Medical Officers of Health. The action of the town council of Ilkeston brings into prominence the urgent need of an alteration of the law which renders such conduct possible.

THE COMPETITION OF HOSPITALS AND PRIVATE PRACTICE.

THE Great Northern Central Hospital, as competing with private practitioners for pay patients, has a companion from whom we might have expected better things. The *Evening Standard* gives an account of an entertainment at Guy's Hospital, partly for the pleasure of the patients in the Bright Ward, but "chiefly for making better known the paying ward of that name," where for three guineas a week medical, surgical, and obstetric cases are received. True, they are not treated by the honorary staff, as in the Great Northern Central Hospital. They are under the care of a gentleman "whose treatment has won for him the confidence and regard of all the patients." It is enough to disturb the repose of the illustrious man after whom this ward is named to think that any part

of Guy's Hospital should have come to such uses. Not to go so far back, there is an eminent consulting surgeon of this hospital who occasionally favours the profession with addresses on subjects touching the interest of practitioners who cannot, we think, approve of such arrangements. This is a deliberate attempt to attract a kind of medical practice which there is no excuse for hospitals seeking to attract. The eulogistic notice of the resident medical officer may be permissible in the new code of hospital medical ethics; but if any private practitioner were to be similarly noticed in the local paper of his district he would justly be liable to criticism by our correspondents and by ourselves. We appeal to the staff of Guy's Hospital to protest against this abuse of their great institution, which was founded for the relief of the poor. The evil we describe is a very grave one, and the leaders of the profession will lose all credit for sympathy with their brethren if something is not done to stop it.

DIPHTHERIA IN LONDON.

THE diminution in the fatal cases of diphtheria witnessed in the concluding week of last year has not only not been maintained, but there has been again, as has so often happened in the present prevalence, a marked increase after the very temporary lull. With the close of last week the number of diphtheria patients remaining under treatment in the hospitals of the Metropolitan Asylums Board was, it is true, brought down to a unit below 500, as compared with 521, 510, and 521 in the preceding three weeks, and the admissions from 111, 80, and 75 in the same three weeks to 62 last week; but the gain thus made has to be set against a death roll of 50, or 17 in excess of the corrected average. True, this number was six times exceeded in the previous twelve weeks, but the deaths in the last fortnight of December had only been 36 and 35 respectively. Diphtheria in London was last week fatal to the extent of some 28 per cent. of the fresh cases, but little more than one-third of these were admitted to hospital. Enteric fever, on the other hand, was fatal to some 17 per cent. of cases, 24 per cent. of which found their way to hospital. Of the 50 diphtheria deaths 30 occurred in children aged from one to five years, and included 5 from Hackney, 4 each from Kensington, Hammersmith, Poplar, and Battersea, and 3 each from Fulham, Islington, Mile-end Old Town, and Greenwich. In Greater London there were 18 deaths, including 5 in West Ham, 3 in Kingston, and 3 in Romford, as well as 1 each in Tottenham and Hornsey.

COLLECTIVE INVESTIGATION UPON THE SERUM TREATMENT OF DIPHTHERIA.

THE editors of our enterprising contemporary, the *Deutsche Medicinische Wochenschrift*, Drs. Eulenberg and Schwalbe, have initiated a plan for the collective investigation of the experiences of the medical profession regarding the treatment of diphtheria by antitoxin. They point out that the results so far published from private practitioners, as well as those from hospitals, speak favourably of a method which may prove to be of the highest importance in therapeutics—a method which has impressed even the most critical, as exemplified in Professor Virchow's declaration that it is the duty of every practitioner to employ it in this disease. They say that scepticism is never more legitimate than in respect to the alleged efficacy of treatment, especially of any treatment that claims to be specific, and that diphtheria affords scope for arriving at a correct judgment upon the results of treatment; but the number of points to be determined are exceptionally numerous and involve many considerations such as can only be gathered on a large scale and over a large area. The question must embrace facts from thousands of cases collected from all sources and from all parts of the

country: hence the idea to undertake a collective investigation throughout Germany similar to that pursued in influenza by the Berlin Society of Internal Medicine, on the lines originated by the British Medical Association. In this scheme they have the support of Drs. Leyden, Litten, Renvers, Heubner, Behring, Ehrlich, and Guttstadt. The cards to be filled up by practitioners can be obtained from the office of the journal. It is proposed to close the inquiry on April 1st, 1895. Whilst expecting no final judgment on the serum question from this inquiry, it is hoped that there will result more certain grounds for its therapeutic employment than hitherto, and that it may serve to solve some doubts as to its value.

"THE LANCET" RELIEF FUND.

THE "Application Form" of THE LANCET Relief Fund will be found in our present issue. It can easily be removed, filled up, and forwarded to the Secretary, Mr. Edward Davies, THE LANCET Offices, 423, Strand, London. We take the opportunity of directing the attention of those of our readers who may have occasion to employ the form or to sign one of the required accompanying certificates to the necessity of carefully noticing the conditions on which applicants become entitled to a participation in the benefits of the Fund.

DEATHS OF THE AGED AND LONGEVITY.

THERE is a certain grimness of humour in the persistence with which paragraphists, on the advent of cold or foggy weather, which is invariably fatal to many old people, summarise the deaths of octogenarians and nonagenarians announced in the obituary columns of the daily press and head their paragraphs "Longevity." It is, to say the least, paradoxical that exceptional mortality among the aged should be referred to as evidence of longevity. An industrious correspondent of a contemporary recently reported that the obituary columns of that paper during 1894 announced the deaths of 196 nonagenarians, of whom 89 were males and 107 were females; and, as is usual in these communications, the correspondent adds that their "aggregate ages were 18,203 years." It is such useless figures as these that bring discredit on statistics. They convey no definite idea and do not even suggest whether we should be struck with the number being high or low. Probably not many of these paragraphists and correspondents have the slightest idea of the fact that at the last census in 1891 no fewer than 9185 nonagenarians were enumerated in England and Wales; and that as, according to the English Life Table, rather more than one of every three living nonagenarians dies annually, it follows that more than 3000 nonagenarians die in England and Wales annually. Of what possible interest, therefore, is it to know (that, of the 3000 nonagenarians whose deaths were probably registered in England and Wales in 1894 196 had their deaths announced in any particular obituary column. As evidence, however, of the greater longevity of females it is worth noting that of the 9185 nonagenarians enumerated in 1891 6173 were females and only 3012 were males. The English Life Table, notwithstanding this disparity, shows but slight difference between the rate of mortality of male and of female nonagenarians, although this difference is, of course, in the favour of females.

THE LATE DR. BROWN-SÉQUARD.

THE January number of the *Comptes Rendus de la Société de Biologie* contains an appreciative notice by the President, M. Eugène Dupuy, of the life and work of the remarkable man—certainly one of the most striking figures in the history of experimental physiology and of clinical medicine—whom death a short time ago removed from among us. Born in

Mauritius, the son of an American and a Frenchwoman, he lived, as all our readers know, and practised successively in France, the United States, and in this country, passing the last twenty years of his distinguished career once more in Paris, with which city he had always kept up the closest ties. M. Dupuy does full justice to the work of the subject of his address, cosmopolitan and extensive as it was. Dr. Brown-Séguard, according to him, was characterised by an enthusiasm, an acuteness, and in particular a capacity for seeing the bearing of his own observations on other men's difficulties that are rarely met with in combination. In this country he devoted himself chiefly to elaborate investigation into the physiological and pathological working of the nervous system, being one of the original staff of the National Hospital for the Paralysed and Epileptic, and there receiving the coöperation of Sir J. Russell Reynolds, Dr. Hughlings Jackson, and Dr. Buzzard among others. His lectures at this institution, which has no counterpart, says M. Dupuy, except the Salpêtrière in Paris, were published in THE LANCET, and stimulated the scientific study of epilepsy and of paralysis due to disease of the spinal cord which have led to marked advance in our knowledge of those obscure diseases in the last twenty years. As a physiologist, as a physician, and as a man who, through numerous vicissitudes and much trouble, found time to accomplish as much work as would suffice for several men of great capacity, his name will always be held in honour in the world of science. No one can read the graceful tribute of M. Dupuy to his memory without a feeling of admiration for its subject.

THE Home Secretary has consented to receive a deputation from the United Kingdom Police Surgeons' Association this month, on a day to be fixed later. The deputation will bring before him the following points: (1) the inadequate amount of the fees and allowances to medical witnesses attending distant sessions and assizes; (2) the importance of issuing the instructions given to the metropolitan police for the examination of persons charged with criminal assaults on females to all provincial police authorities; (3) the desirability of having a police surgeon appointed in all counties and towns where none at present exists; and (4) to ask that, in the event of medical certifiers of the cause of death being appointed, the interests of police surgeons may be safeguarded.

ON Thursday, Jan. 3rd, Dr. Patrick Heron Watson, F.R.S. Edin., Surgeon-in-Ordinary to the Queen in Scotland, was entertained at a dinner in Edinburgh by his former house surgeons and presented with his portrait, and an album containing the photographs of the subscribers. The portrait was painted by Sir George Reid.

THE Lettsomian Lectures will be delivered before the Medical Society of London on the evenings of Mondays, Jan. 21st, Feb. 4th, and Feb. 18th, by Dr. F. T. Roberts, the announced subject being the Combinations of Morbid Conditions of the Chest.

MR. F. J. WALDO, M.A., M.D. Cantab., D.P.H., medical officer of health to St. George's, Southwark, and to the Inner and Middle Temples, has been appointed Tutor in Public Health to St. Bartholomew's Hospital Medical School.

A CONFERENCE in connexion with the Matrons' Council will be held on Thursday, Jan. 17th, at 8.30 P.M., in the Medical Society's Rooms, 11, Chandos-street, Cavendish-square, when a paper entitled "Infirmary Matrons under the Poor-law" will be read by Miss Mollett, matron to the Royal South Hants Infirmary, Southampton.

CASES TREATED BY THE TALLERMAN-SHEFFIELD DRY AIR BATH AT THE NORTH-WEST LONDON HOSPITAL.¹

BY J. F. SARJEANT, M.R.C.S. ENG., L.R.C.P. LOND.,
RESIDENT MEDICAL OFFICER.

THE authorities of the North-West London Hospital having at the suggestion of Mr. Mayo Collier kindly consented to submit a series of cases to treatment by the "local and medical dry air bath," the proprietors of that apparatus courteously placed one of their cylinders at the disposal of the medical staff for that purpose, and I give the notes and results obtained during the past two months. It might not be out of place to refer here to the fact that this apparatus was introduced to the medical profession by Mr. Willett at St. Bartholomew's Hospital, in the wards of which institution a variety of cases were treated for two months, after which Mr. Willett detailed the results obtained in a clinical lecture delivered on May 23rd last. Acting upon the suggestions thrown out by the lecturer on that occasion several medical cases were treated. The operation extends over forty minutes at an average temperature of from 240° to 260° F., and may be shortly described as follows. The affected part is placed in the cylinder, which, to save time, has been already heated to a temperature of 150° and is then gradually raised. The system of heating and ventilation admits of the air in the cylinder being kept practically dry throughout the operation, thereby enabling a very high temperature to be borne by the patient, in one instance at St. Bartholomew's Hospital reaching 300°, whilst temperatures from 270° to 280° are by no means unusual. Under treatment patients experience a sense of comfort, probably due to the high temperature exercising an anodyne influence, which relieves the pain, or more often removes it entirely; even when adhesions have been broken down the pain is much modified if the joint is immediately subjected to treatment. Some of the cases can hardly fail to be of interest, being of that chronic character for which so little can be done by ordinary medical treatment; all of them were selected for their severity in order to test to the utmost the value of the apparatus; the majority were cured and the remainder exhibited such marked improvement that it is only fair to state that there was not a single failure. Mr. Lewis A. Tallerman kindly gave his personal attention during the treatment, and Mr. Mayo Collier supervised the selection of the cases.

CASE 1. Sprain.—A child eleven years of age. The right ankle and foot were swollen, tender, and painful, with great pain on movement and inability to put the injured foot to the ground. There was a good deal of effusion, both into the tendon sheaths and into the joint itself.—First operation (Aug. 13th), forty minutes: the pain was found to have almost disappeared, there was considerably less effusion, and the foot could be put to the ground.—Second operation (14th), thirty-five minutes: further improvement, with power to flex and extend the ankle.—Third and last operation (16th), thirty minutes: the effusion was entirely absorbed, the patient could walk well and without pain. He was discharged as cured.

The result of the treatment in this case was very satisfactory, a severe sprain having been cured after three operations given in four days, the temperature of the cylinder varying from 200° to 220° F.

CASE 2. Acute attack of gout following sprain of right ankle.—A man fifty-seven years of age. The patient sprained his right ankle on Aug. 11th by striking it against a stack of iron. On the day after the injury he had a typical attack of gout in the great toe of the injured foot, and stated that he had been unable to sleep for two nights and was in great pain. On examination the right ankle and foot were very much swollen, the ankle-joint was filled with fluid, and the entire surface reddened and shiny. Acute tenderness was present over the whole foot, especially over the tarso-metatarsal joint of the great toe. All movements were painful and the foot could not be put to the ground.—First operation (Aug. 14th), forty minutes: after the bath the pain and tenderness to pressure and movement had gone from the ankle-joint and the

pain and tenderness in the great toe were much modified.—Second operation (15th), thirty minutes: the patient had passed a good night, and after the operation he was able to stand.—Third operation (20th), thirty minutes: on examination there was no pain or tenderness on movement or pressure, and the patient was able to walk; some redness still remained.—Fourth operation (21st), forty minutes: the swelling was almost gone; no pain or tenderness was present.—Fifth operation (23rd), forty-five minutes: the patient reported that he had been able to walk for twenty minutes without pain; all effusion had disappeared and the ankle and great toe were now freely movable and without pain. Being considered in a fit state to resume his ordinary duties he was discharged.

The temperature in this case was maintained at from 230° to 240° F., and the result obtained was most satisfactory. The pain was relieved almost at once, the effusion rapidly disappeared, and the patient was cured of a bad attack of gout with a severe sprain in twelve days.

CASE 3. Chronic rheumatoid arthritis.—A woman sixty-four years of age. Both knees, shoulders, and wrists, and all the finger-joints were affected. The patient had been under hospital treatment for four years without improvement—four months at the University College Hospital and two years under Dr. Sibley at the North-West London Hospital. On examination all the finger-joints were found to be enlarged and painful, and there was great limitation of movement, the patient not being able to flex the fingers on the palm. The movement of both wrists was limited and painful. The right elbow was fixed at a right angle, and any attempt at movement caused great pain. Both knees and shoulders were enlarged and painful, and distinct grating could be felt on movement. This patient was first treated in the hot air cylinder on Aug. 10th. After the first operation it was noticed that the pain was considerably less and the joints showed marked improvement. After the fourth operation the patient, who had been unable to work at her business for eighteen months, was again able to use her needle. After the fifth operation the right arm could be fully extended without pain, and with a little pressure the fingers could be flexed on the palm. The left hand and arm also showed marked improvement, although they had not been treated in the cylinder. After the eighth operation, with the exception of the first finger, in which a little stiffness still remained, all the fingers closed readily. On Aug. 24th, after the ninth operation, the patient reported having resumed her former occupation and her ability to walk up and down stairs without pain. The patient has been kept under treatment up to the present date and shows continued improvement. The average length of each operation was about forty minutes, and the temperature was averaged 240° F.

This case of chronic rheumatoid arthritis had been under continual medical supervision from its onset and the usual remedies were applied. Its history shows that, so far from yielding to treatment, the disease made rapid strides; so much so that whereas eighteen months ago the patient was able with some effort to follow her occupation of dress-maker, twelve months later she was incapacitated from even feeding or dressing herself. The improvement wrought by the hot dry air cylinder was as immediate as it was remarkable; the progress of the disease was arrested, and a curative process was set up at the first operation, which became more manifest with every succeeding one, proving beyond doubt the value of the treatment in cases of this nature.

CASE 4. Old tuberculous knee-joint.—The patient was twelve years of age. In this case the knee-joint had been kept at absolute rest in plaster of Paris for upwards of seven months. On removing the splint the disease was found to have disappeared, leaving little or no movement, any attempt to increase it causing severe pain. After six operations the movement had increased from 45 to 50 degrees, there was no grating in the joint, and the patient could walk freely and well; no forcible movement was used. The temperature in the treatment of this case rose to 220° F.

CASE 5. Chronic ulcer of leg.—A woman forty-five years of age. The patient had suffered from chronic ulcer of the right leg for the last five years. She was treated at the North-West London Hospital as an out-patient without improvement, and was an in-patient at the Temperance Hospital for six weeks, at the end of which time the ulcer was healed. Two years ago the ulcer broke out again after a fall and had been getting worse ever since. On examination a large unhealthy ulcer about the size of the palm of the hand was found on the front of

¹ Inquiries respecting the above-mentioned apparatus should be addressed to the secretary, Mr. M. St. B. Prichard, at the offices of the proprietors, 1 and 2, Chiswell-street, Finsbury-square, London, E.C.

the right leg above the ankle; the edges were unhealthy and the base was covered with thin white slough. There was a loss of tissue of about $\frac{1}{4}$ in. in depth. The patient was treated twice in the hot dry air cylinder, each operation averaging thirty-five minutes, at a temperature up to 245° F. The base of the ulcer was then found to be much cleaner and the margins showed signs of healing. About fourteen days later the patient was seen by Mr. Mayo Collier, who found that the lost tissue was replaced, the ulcer had filled up, the margins showing further unmistakable signs of healing.

CASE 6. Chronic rheumatoid arthritis.—A man seventy-one years of age. The disease was of twelve months' duration. Both elbows and all the joints of the fingers were stiff and painful, so much so that it was with the greatest difficulty that he continued to work at his trade. After five operations the improvement in this case, both as to pain and stiffness, was so marked that he was enabled to go to his work without inconvenience.

CASES 7 AND 8. Sprains.—The first of these cases was that of a man twenty-two years of age and the second that of a man twenty-four years of age suffering from sprained ankles with the usual severe symptoms. Each was treated on five occasions with most satisfactory results. The pain in both cases had disappeared after the second operation and the joints were quite sound after the fifth.

Remarks.—It must be confessed that the results obtained by the usual treatment in cases of chronic stiffness of joints are far from satisfactory, so that one is inclined to welcome all the more cordially a recent therapeutic method which claims, and apparently with justice, to remove, at least in part, this reproach from surgery. The Tallerman-Sheffield local dry hot air bath is an invention by which dry air at temperatures from 250° to 300° F. is applied to a portion of the body, such as hand or foot, knee or elbow, an arm or leg. In May of last year Mr. Alfred Willett delivered a clinical lecture at St. Bartholomew's Hospital on some cases which he had treated by this method; and the present list consists of a series of eight cases in which this bath was employed at the North-West London Hospital, under the care of Mr. Mayo Collier. The bath itself consists of a copper cylinder, varying in size and shape according to the part to be enclosed. At one end the limb enters, surrounded by rubber sheeting, and the other is closed by a movable cap working on a pivot, by the use of which, and outlets at the top and bottom of the cylinder, it is found possible to keep the air in the chamber practically dry throughout the operation, notwithstanding the moisture thrown off by the limb enclosed, and instant relief can be afforded the patient if the temperature causes any discomfort. The cylinder is heated by gas burners placed underneath. Precautions are taken to prevent the skin from coming into contact with the heated metal. Mr. Willett's conclusions are decidedly in favour of the treatment in certain cases, and his results may be summarised as follows. The first effect of the heat is to induce a copious diaphoresis; and the circulation of the blood in the part is enormously increased, as is well shown by the bright redness of the limb when removed from the bath. The anodyne effect is often remarkable; pain is generally not only relieved but entirely removed, so that the patient expresses the great relief he feels and moves the limb with much greater freedom and with much less pain. The cases that appear the most likely to be relieved by the treatment are sprains, stiff joints (where there are no very strong adhesions), flatfoot, gonorrhoeal rheumatism, acute and chronic gout, chronic ulcers, and rheumatism. It deserves also to be employed for its anodyne effect after forcibly breaking down under an anæsthetic adhesions which have formed in or around a joint; if the limb be placed in the cylinder the pain, which is generally severe, is greatly lessened and the secondary stiffness is much diminished. Mr. Willett was of opinion that but little assistance would be afforded by this bath in overcoming firm, fibrous, articular adhesions. Sooner or later the adhesions will have to be forcibly broken down under an anæsthetic, but, such having been done, I think the recovery will in many cases be hastened by the subsequent use of the heated cylinder. In other words, while facility in active movements is immensely increased, the range of movement is not extended to any great amount. The results obtained in the cases treated at the North-West London Hospital endorse the favourable opinion of Mr. Willett, and the benefit to be derived in rheumatic arthritis is shown in two cases, and in gout in one. The general effect of the baths is marked, but

apparently in no way injurious. The entire skin is relaxed and perspires freely, and pain is relieved in joints other than those enclosed in the cylinder.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

[This report appeared in our Second Edition last week.]

A MEETING of the Fellows of the Royal College of Surgeons of England was held on Thursday, Jan. 3rd, the President, Mr. J. W. Hulke, F.R.S., being in the chair.

The Chairman reported that, in reply to the resolution adopted at the last meeting of Fellows requesting the Council to take steps for obtaining the opinion of the Fellows on the mode of election to the office of President, the Council on July 30th last adopted the following resolution—viz.: "That the Council are not prepared at the present time to consult the Fellows, or solicit their opinion through other means than the meetings of Fellows. They, however, point out that if any Fellow is anxious to test the opinion of the general body as to whether it is desirable to make any change in the present mode of election of the President it is open to him to submit a motion on the question to the meeting of Fellows in January or subsequently."

Mr. Herbert W. Page, on behalf of the Society of Fellows, communicated the result of a canvass, made by the Society, of all Fellows resident in Great Britain upon the mode of election to the office of President. Three propositions were suggested:—

1. That the President should be elected by the Fellows.
2. That the President should be nominated by the Council and elected by the Fellows.
3. That the President should be elected by the Council as at present.

A thousand voting papers were sent out and 468 papers were returned, but of these 50 were useless. For the first proposition, 112 voted; for the second, 156; and for the third, 150.

Mr. Page considered that the result of the canvass indicated that no alteration in the present mode of election was desired by the great body of Fellows.

Mr. Craven saw no reason for any change.

Mr. Rivington considered that the canvass was decidedly in favour of a change, as 268 Fellows voted for the first and second propositions; he was decidedly in favour of a similar canvass of the Fellows being taken by the Council.

Mr. Howard Marsh said that the Council were often asked to make changes which were *ultra vires*, and contended that they always worked earnestly for the good of the College.

Mr. Bell of Rochester was in favour of a nomination by the Council and an election by the Fellows.

Mr. Howse saw great difficulties in any form of nomination by the Council and election by the general body of Fellows.

Mr. W. H. Bennett then moved: "That the Council be requested to appoint a Conjoint Committee of members of the Council and other Fellows of the College to consider the desirability of obtaining a new Charter, together with the details thereof." He thought that the question whether a new Charter was needed or not should be settled once for all; he contended that the resolution was in no way antagonistic to the Council.

Mr. Holmes seconded the resolution, and said that it was very important that the general body of Fellows should have a voice in determining any vital change in the constitution of the College and its relations to other public bodies.

The President said it appeared to be forgotten that the Council had already pledged itself to bring all important matters before the Fellows before coming to a decision on them.

On being put to the vote, the resolution was carried, 22 voting in its favour and 14 against.

The resolution standing in Mr. F. J. Gant's name was not brought forward, being almost identical with that just voted on.

In a few concluding words the President regretted that the resolutions brought forward at these meetings dealt only with the constitution of the College, and did not deal

with educational matters, which were really of much more pressing importance.

Forty-six Fellows were present altogether, but the meeting had assembled some minutes before the quorum of thirty was obtained.

SANITATION AT THE CAPE OF GOOD HOPE.

THE annual report for 1893 on the public health of the Cape, which Dr. A. J. Gregory has, by command of the Governor, presented to both Houses of the Cape Parliament, contains much interesting matter. It is framed somewhat on the lines of a county medical officer's report in this country—i.e., it consists of a comprehensive digest of the sanitary condition and requirements of the colony as culled from the reports of the district surgeons and other sources, while in the appendix the district reports are given in full. The care of the public health by the Cape Government is, Dr. Gregory remarks, an affair of but very recent development; indeed, it was not until the year 1891 that a separate Local Government and Public Health Department was organised, and only during the session of 1892 did the Cape Parliament vote a sum of money for procuring expert advice and guidance upon sanitary matters. Under circumstances such as these it is hardly to be expected that the public health service of the colony should be other than somewhat embryonic. The department has as yet no power by which it can compel sanitary authorities to carry out their obligations, such as is possessed by the Local Government Board in this country, and the difficulties in the way of obtaining reliable information as to the vital statistics of the several districts are enhanced by the absence of any proper system of registration of births and deaths, and of notification of infectious diseases. The Public Health Department communicates by letter with sanitary authorities in reference to the more urgent requirements of their district, but in some cases the communications are not even acknowledged by the authorities in question; and a comparison of the district reports of 1892 with those of 1893 shows that but very few reforms have been effected in the interval. Only a very small proportion of the sanitary authorities in the colony have provided anything in the shape of isolation accommodation; but we are glad to see that there is a prospect of proper provision being obtained by the several authorities of the Cape peninsula, both in regard to small-pox and other infectious diseases. The provisions of the Contagious Disease Prevention Act, 1835, have, where carried into operation, resulted in diminished venereal disease both among prostitutes and the Imperial forces; it seems, however, that in Capetown itself there exists a large amount of irregular or casual prostitution which is not reached by the Act. In dealing with the communicability of syphilis Dr. Gregory refers to the remarkable manner in which the disease seems to spread from person to person under the conditions in which the native population live, altogether apart from the direct effect of sexual intercourse, and he quotes from several of the district reports cases in which Europeans have contracted the disease from the native servants and children. For instance, the district surgeon of Calitzdorp remarks that, of 36 European cases in his district, only 4 can be said to have contracted the disease through immorality, the remaining 32 having been directly or indirectly inoculated from coloured persons. By way, too, of demonstrating the heavy incidence of the disease upon innocent children Dr. Gregory divides those affected with syphilis into two groups—those above and those below fourteen years of age; and he assumes that in the latter group the disease is always innocently contracted. He found as a result of his analysis that 35 per cent. of the whole number were children under fourteen years of age. Again, the district surgeon of Oudtshoorn remarks that the disease is often conveyed between children using the same spoon or the toy known as a mouth-organ.

In regard to leprosy some interesting tables are furnished in Dr. Gregory's report, and from these he concludes that—(1) leprosy is five or six times more prevalent among natives and coloured persons than among whites; (2) Europeans appear to be less frequently affected in those districts in which the native element is less likely to be intimately associated with the European; and (3) the prevalence of the disease increases in direct ratio to the density of the population.

These conclusions, Dr. Gregory observes, seem to point to the contagiousness of leprosy, and also to the fact of the contagiousness being slight in comparison with other infectious diseases, as otherwise the disease would long ago have disseminated itself fairly evenly throughout the colony.

Small-pox was introduced into the colony during 1893 by several of the mail steamers from England, and quarantine was extensively resorted to in order to check its spread. Much delay, inconvenience, and expense were occasioned, but it is satisfactory to learn that as a result of the alarm produced by the presence of small-pox a decided impetus to sanitation was given throughout the colony. The occurrence has, Dr. Gregory remarks, been very instructive, and it suggests, he says, among many other points, the question as to whether a system of medical inspection, proper disinfection, isolation, &c. might not be substituted for the cumbersome and costly machinery of quarantine.

The Cape Government has ceased to import calf lymph from England owing to the fact that the lymph, on account either of the excessive heat or delay in transit, was often inert when used, and a calf vaccine station has been started at Grahamstown. Epidemic pneumonia occurred in several districts of the colony during 1893, and in Kimberley 365 deaths were attributed to the disease. Puerperal fever seems to have been rife in many districts, and ignorant midwives were frequently instrumental in spreading the disease.

In concluding his report Dr. Gregory urges upon the Government the absolute necessity which exists for legislative measures "investing a central authority with power to supervise and guide the local authority in the exercise of its functions; without such powers I am convinced that the public health of the colony can never be properly conserved."

OBSERVATIONS ON THE MEDICAL DEPARTMENT OF THE BRITISH ARMY BY AN OFFICER OF THE UNITED STATES MEDICAL SERVICE.

WE recently very briefly adverted to Brevet Lieutenant-Colonel Woodhull's Observations on the British Medical Service, abridged from an official report and published by authority of the Secretary of War of the United States. These observations are reprinted from the fourth volume of the Transactions of the Association of Military Surgeons of the United States. The writer of this abridged report is a distinguished officer of the American Medical Service, and he is certainly to be congratulated on the ability and accuracy with which he has discharged the duty committed to him. Whilst in England in 1891 he was ordered by the War Department of the United States to make the utmost use of such facilities as might be granted to study the British military hospitals, the army medical school, the duties of medical officers, the sanitary administration of barracks and camps, the instruction service of the Medical Staff Corps, and the system of physical training in the British army. It will be seen that the scope of his inquiries was sufficiently comprehensive, and he has evidently been indefatigable in his efforts to obtain a good firm grasp of his subject. The results are embodied in the abridged report before us. It is surprising what an amount of well-arranged information Colonel Woodhull has managed to incorporate in a condensed form in this report, which should, and probably will, be extensively read by medical officers of the British service. Sydney Smith humorously traced how taxation shadowed every step and stage in the career of a British subject, and Colonel Woodhull has, it may be said, in a similar manner traced the British soldier from the cradle to the grave; he has described and analysed our army medical regulations, our service customs and practices, as contrasted with those of his own service, and in a running commentary frankly reviewed our methods in an honest, independent spirit, but always in excellent taste.

From what we have said it will be seen that it is impossible, nor indeed is it necessary, to accompany Colonel Woodhull through all his inquiries and comments; we can only attempt to select a few points. Passing over his general remarks on the strength and organisation of the British medical department, the entrance examination and the course

at Netley, and the system of promotion in the various grades and the duties assigned to each of them, he points out, *en passant*, some minor practical differences between the medical service of this country and that of the United States, and adverts to the subject of the roll of married soldiers in the British army, which, judged by any ordinary measure of a combatant force, is, he says, enormous and draws deeply on the medical as well as on the other resources of the establishment. Much consideration is given to the subject of diets in British and American army hospitals and the different systems on which these are based respectively. The dietary of the United States hospitals is, it may be mentioned, very liberal and varied, and it is so different from that of our army that no useful comparison can well be made. Speaking of medical history sheets—which we regard as excellent and most useful documents in our service, with its soldiers serving in all parts of the world—Colonel Woodhull does not, on the whole, and for the reasons he gives, think that their adoption in the American service would be attended with any great advantage. As regards the nursing sisters of our service, he says that he formed a very favourable impression of this trained section of the nursing staff. Alluding to the functions and authority of the director-general, he remarks that these greatly transcend those of the surgeon-general of the United States army, and he goes on to make some judicious remarks on promotion by selection and seniority. “By restraining promotion in the lower and medium grades to seniority, moderate ambition and moderate abilities are satisfied; and opening the higher ranks to choice presents a stimulus for exertion, and relieves the administrative positions from the inertia and indifference that sometimes accompany age.” Colonel Woodhull has a good deal to say about recruiting, and particularly about the Medical Staff Corps. Like anybody else who has any practical knowledge of the subject, he is opposed to the limitations of stature now in force for the men of this corps, unfitting them as they do for the work they will have to perform in war. His comments on the Aldershot system of training of the Medical Staff Corps are very favourable, although he considers that in several particulars the methods pursued in the United States Service are simpler and better adapted to the general end in view, and therefore to be preferred. In connexion with this subject we may say that Colonel Woodhull expresses his surprise that the Army Medical Service and Medical Staff Corps are not more practically utilised at our autumn manoeuvres than they are.

Colonel Woodhull also considers that his army service has nothing to acquire from Great Britain in the system of tentage, whether considered for shelter, artificial warmth, convenience of transport, or adaptability to campaigning purposes.

Speaking of our barrack-rooms, he thinks that the men can hardly be warm enough for comfort, and this is a matter in which they would certainly agree with him, for the insufficient allowance of fuel and the draughty nature of these rooms in cold weather are common complaints with soldiers.

Referring to the subject of medical and sanitary instructions for field service, we are glad to notice that he gives some extracts from those issued in this country for the Suakin Expedition, which he very highly commends for their scope, intrinsic value, and general usefulness, expressing at the same time his regret that he failed to note the name of the officer who prepared these valuable memoranda. We may here incidentally remark that THE LANCET drew special attention to the excellence of these instructions at the time they were issued. Colonel Woodhull devotes much consideration to Netley and to the value of such an institution to the State and the army. Although the courses at Netley and Aldershot overlap in some respects, he holds that, taken as a whole, “they are both admirable, and are strongly commended for our imitation.”

With reference to the various forms of transport for wounded he saw nothing as regards comfort and economy of force and the requirements of the American army to approach the *travois* and the *Baily litter*.

Colonel Woodhull's remarks on gymnasia and the physical training of the British soldier strike us as pertinent and good. The physical development of the soldier, in whom the fighting instinct is naturally strong, gives to the British army, he says, much of the formidableness it possesses, notwithstanding certain deficiencies in the original material and other incidental conditions of the service.

But here we must stop, contenting ourselves with hoping

that we have said enough to show that the report under review is both interesting and instructive, and consequently well worth reading.

THE CLUB SYSTEM IN CORK.

(FROM A CORRESPONDENT.)

FOR a number of years it has been a standing grievance with the profession in Cork that amongst the members of the Odd Fellows and kindred societies are many who are well able to pay ordinary medical fees, amongst them being owners of large business establishments. The secretaries and individual members of these clubs have been privately remonstrated with from time to time, but without effect, the almost invariable reply being: “Those are the very men we wish to get hold of. They give stability to our club. They are not likely to draw sick pay, and that is all the better for our other members.” The obvious inference is that the clubs cared little to what extent the medical men were—I had almost said—swindled out of their legitimate fees, provided the funds of the club at the end of the year were benefited to the extent of a few paltry shillings. But what mainly brought matters to a crisis has been the formation in late years of quite a number of clubs bearing such high-sounding names as “medical aid associations.” These clubs were formed solely to procure the services of some local practitioner, and he generally received the splendid remuneration of £1 per member per annum, which sum included medical attendance, not alone for the member, but also for his family. It is hardly credible, but yet the fact, that amongst the members of these associations are to be found captains of large steamers, managers of banks, and heads of Government departments. When the medical men eventually combined to resist this intolerable state of affairs resistance came mainly from the older benefit clubs; but the probability is that if the general body of the members of those clubs had been left to their own honourable promptings the difficulty would have been got rid of very quickly. However, such was not the case. At the instance of some of the secretaries whose salaries depend on the number of members a meeting of delegates was held, and one of the latter, who has turned thousands a year in business, denounced the audacious attempt of the medical men to deprive him of the privilege of having himself and his family provided with medical attendance and medicines for the very handsome sum of 15s. per annum, or 3½d. per week. The eloquence of such interested gentlemen, I regret to say, prevailed with the working men, who form a large proportion of those clubs. The newly formulated rules of the medical men were contemptuously sent back to them, and surprise was afterwards expressed because this silly impertinence was treated by the medical men with dignified silence. Whilst harmless talking has been done by a section of the club members the medical men have quietly perfected their organisation, and, with a solitary exception, they are united in one solid phalanx. Though they have not the slightest objection to see working men and clerks with small salaries in clubs, yet they are quite determined to put an end to any system which will permit gentlemen in receipt of £600, £800, or £900 a year to claim medical services for 15s. or £1 per annum. It seems to be the merest question of “live and let live.” It must be said that it is highly creditable to the profession in Cork that there is only one of their number who stands aloof from their organisation. This gentleman is, I understand, quite a recent importation, and there is no doubt the spirited representatives of the profession in Cork can well afford to ignore his action, which can hardly be regarded as calculated to improve the status of the profession of which he happens to be a member. The temptations to outsiders to follow his example are not very alluring. It has been calculated that after deducting the cost of medicines less than £500 a year has been received by the profession from twenty of the ordinary benefit clubs, including Foresters, Odd Fellows, &c., though members of those clubs have been deluging the local newspapers with statements that their societies paid thousands a year to the medical practitioners of Cork. Already one of the principal medical aid associations has been voluntarily wound up, without waiting for the advent of the new year, when the rules of the profession are to come into force. Some of the benefit clubs have also taken time by the forelock and intimated their intention of meeting the wishes of the medical men; and now that

the rank-and-file of those clubs realise that the medical men have really no contest with them and merely wish to insist on the well-to do members of those clubs paying for medical services in accordance with their means it is expected that the new year will be yet young when the public opinion of Cork will insist that meanness amongst a certain class of the citizens will be stamped out and that the eminent services of the Cork medical practitioners should be recognised by fair and just remuneration.

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THIS society has been formed to continue the work of the late Association of Members of the Royal College of Surgeons of England, and will have the following objects:—

1. To arouse and maintain among the Members a permanent interest in their College by giving them a share in its management.

2. To promote the acquisition of a Charter by the College, which shall permit the Members to take some part in the election of the Council.

3. While seeking primarily to further the interests of the Members, to support and coöperate with the Fellows' Societies in obtaining such reforms in the by-laws as are possible under the present Charter.

4. Generally to promote the welfare of the corporation by bringing its at present somewhat inharmonious constituents of Council, Fellows, and Members into united action.

The committee consists at present of Mr. Joseph Smith (chairman), Dr. Danford Thomas, Dr. F. H. Alderson, Mr. Brindley James, Mr. George Brown, Mr. Nelson Hardy, Mr. Thomas Morton, Mr. J. C. Smith, and Mr. W. G. Dickinson, with power to add to their number. The annual subscription is half-a-crown, and the hon. secretary, Mr. W. G. Dickinson, Southfields, London, S.W., will be glad to receive the names of Members wishing to join the Society.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 7410 births and 3844 deaths were registered during the week ending Jan. 5th. The annual rate of mortality in these towns, which had declined in the preceding four weeks from 20.2 to 18.0 per 1000, rose again last week to 18.9. In London the rate was 17.4 per 1000, while it averaged 20.0 in the thirty-two provincial towns. The lowest rates in these towns were 14.1 in Cardiff, 14.5 in Halifax, 14.6 in Plymouth, 15.2 in Bradford, and 15.5 in Blackburn; the highest rates were 24.0 in Brighton, 24.1 in Leeds, 24.3 in Wolverhampton, 24.5 in Preston, and 25.0 in Gateshead. The 3844 deaths included 399 which were referred to the principal zymotic diseases, against 392 and 385 in the preceding two weeks; of these, 125 resulted from measles, 87 from diphtheria, 63 from whooping-cough, 45 from diarrhoea, 41 from "fever" (principally enteric), 35 from scarlet fever, and 3 from small-pox. No fatal case of any of these diseases occurred in Plymouth; in the other towns they caused the lowest death-rates in Cardiff, Brighton, and Manchester, and the highest rates in Portsmouth, Preston, Leeds, Gateshead, and Newcastle-upon-Tyne. The greatest mortality from measles occurred in Derby, Leeds, Newcastle-upon-Tyne, Gateshead, Preston, and Portsmouth; from scarlet fever in Salford; from whooping-cough in Sunderland, Wolverhampton, and Blackburn; and from "fever" in Birkenhead. The 87 deaths from diphtheria included 50 in London, 5 in Birmingham, 4 in Leeds, 4 in Sheffield, and 3 in West Ham. Two fatal cases of small-pox were registered in Birmingham and 1 in Liverpool, but not one in London or in any other of the thirty-three large towns. There were 23 small-pox patients under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 5th inst., against 22, 15, and 16 at the end of the preceding three weeks; 8 new cases were admitted during the week, against 3, 0, and 1 in the preceding three weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1779, against 2034, 1931, and 1890 on the preceding three Saturdays; 126 new cases were admitted during the week, against

161 and 116 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 325 and 332 in the preceding two weeks, declined to 319 last week, and were as many as 449 below the corrected average. The causes of 76, or 2.0 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Bradford, Leeds, and in ten other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Leicester, Huddersfield, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21.7 and 22.1 per 1000 in the preceding two weeks, declined again to 21.8 during the week ending Jan. 5th, but exceeded by 2.9 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13.9 in Paisley and 14.6 in Dundee to 24.0 in Perth and 24.6 in Glasgow. The 630 deaths in these towns included 38 which were referred to measles, 11 to diphtheria, 9 to whooping-cough, 8 to scarlet fever, 8 to diarrhoea, 5 to "fever," and 2 to small-pox. In all, 81 deaths resulted from these principal zymotic diseases, against 111 and 86 in the preceding two weeks. These 81 deaths were equal to an annual rate of 2.3 per 1000, which was 0.8 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 32, 54, and 41 in the preceding three weeks, further declined to 38 last week, of which 18 occurred in Glasgow, 13 in Aberdeen, and 3 in Paisley. The deaths referred to diphtheria, which had been 10 and 4 in the preceding two weeks, rose again to 11 last week, and included 5 in Glasgow, 2 in Aberdeen, and 2 in Perth. The 9 fatal cases of whooping-cough showed a marked decline from the numbers recorded in recent weeks, and included 7 in Glasgow. The deaths from scarlet fever, which had declined from 12 to 8 in the preceding four weeks, were again 8 last week, of which 4 occurred in Glasgow and 2 in Edinburgh. The 2 fatal cases of small-pox were registered in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 142 and 138 in the preceding two weeks, rose again to 154 last week, and slightly exceeded the number in the corresponding week of last year. The causes of 52, or more than 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the preceding three weeks from 27.1 to 25.4 per 1000, rose again to 28.3 during the week ending Jan. 5th. During the thirteen weeks of last quarter the death-rate in the city averaged 23.5 per 1000, against 16.6 in London and 19.6 in Edinburgh. The 190 deaths registered in Dublin during the week under notice showed an increase of 20 upon the number in the previous week, and included 10 which were referred to the principal zymotic diseases, against 22 and 21 in the preceding two weeks; of these, 5 resulted from small-pox, 2 from "fever," 2 from diarrhoea, and 1 from whooping-cough, but not one from measles, scarlet fever, or diphtheria. These 10 deaths were equal to an annual rate of 1.5 per 1000, the zymotic death-rate during the same period being 1.8 in London and 1.7 in Edinburgh. The fatal cases of small-pox, which had been 5, 6, and 10 in the preceding three weeks, declined to 5 last week. During last quarter no fewer than 51 deaths resulted from small-pox in Dublin, of which 27 were registered during the last four weeks of the year. The deaths referred to different forms of "fever," which had been 4, 7, and 3 in the preceding three weeks, further declined to 2 last week. The 190 deaths in Dublin last week included 21 of infants under one year of age and 48 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from those recorded in the preceding week. Seven inquest cases and 6 deaths from violence were registered; and 70, or more than a third, of the deaths occurred in public institutions. The causes of 9, or more than 4 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING DECEMBER, 1894.

In the accompanying table will be found summarised

MONTHLY ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON—DECEMBER, 1894.

(Specially compiled for THE LANCET.)

Sanitary areas.	Estimated population in the middle of 1894.	NOTIFIED CASES OF INFECTIOUS DISEASE.										DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.										Deaths of infants under one year to 1000 births.				
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Bubonic fever.	Other con- tinued fevers.	Puerperal fever.	Krysipelas.	Cholera.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.†	Whooping- cough.	Typhus fever.	Bubonic fever.	Other continued fevers.	Diarrhoea.		Total.	Annual rate per 1000 persons living.	Deaths from all causes.	Death-rate per 1000 living.

* Including 36 cases of membranous croup.

† Including deaths from membranous croup.

complete statistics relating to sickness and mortality during December in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases in the accompanying table was equal to 8·4 per 1000 of the population, estimated at 4,349,166 persons. In the preceding three months the rates had been 9·6, 10·0, and 9·5 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Hampstead, Stoke Newington, St. Giles, City of London, Lewisham, Woolwich, and Lee; while they showed the largest excess in Fulham, St. James Westminster, St. George-in-the-East, Poplar, Rotherhithe, Battersea, Greenwich, and Plumstead. The prevalence of small-pox in London showed a further decline during December, only 17 cases being notified during the month, including 11 in Marylebone, 2 in Poplar, and 1 each in St. Pancras, Whitechapel, St. George Southwark, and Port of London sanitary areas. The Metropolitan Asylum Hospitals contained 16 small-pox patients at the end of December, against 93, 45, and 31 at the end of the preceding three months; the weekly admissions averaged 3, against 17, 9, and 6 in the preceding three months. The prevalence of scarlet fever in London showed a marked further decline from that recorded in recent months; this disease was proportionally most prevalent in Fulham, St. Pancras, Mile-end Old Town, Poplar, Rotherhithe, Battersea, Greenwich, and Plumstead sanitary areas. The Metropolitan Asylum Hospitals contained 1865 scarlet fever patients at the end of December, against 2058, 2207, and 2114 at the end of the preceding three months; the weekly admissions averaged 171, against 245, 246, and 208 in the preceding three months. The prevalence of diphtheria also showed a slight further decline during December; among the various sanitary areas this disease showed the highest proportional prevalence in Fulham, Chelsea, Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, Poplar, and Greenwich. There were 521 cases of diphtheria under treatment in the Metropolitan Asylum Hospitals at the end of December, against 496, 537, and 517 at the end of the preceding three months; the weekly admissions averaged 93, against 96, 100, and 90, in the preceding three months. The prevalence of enteric fever in London showed a further increase upon that recorded in recent months; among the various sanitary areas this disease was proportionally most prevalent in St. George Hanover-square, Westminster, St. James Westminster, Marylebone, St. Martin-in-the-Fields, Strand, and City of London. Erysipelas showed the highest proportional prevalence in Holborn, St. Luke, Shoreditch, Bethnal Green, Rotherhithe, and Battersea sanitary areas. Two cases of puerperal fever were notified in Camberwell, and 2 in Greenwich sanitary areas.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various sanitary areas, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, Dec. 29th, the deaths of 5906 persons belonging to London were registered, equal to an annual rate of 17·7 per 1000, against 14·4, 15·8, and 15·2 in the preceding three months. The lowest death-rates during December in the various sanitary areas were 6·9 in Stoke Newington, 10·2 in Hampstead, 12·0 in St. Olave Southwark, 12·8 in Plumstead, 13·7 in Holborn, and 14·2 in St. George Hanover-square; the highest rates were 23·6 in St. George-in-the-East and in Limehouse, 23·7 in St. George Southwark, 24·9 in St. Saviour Southwark, 27·4 in Woolwich, 27·6 in Strand, and 31·3 in St. Luke. During the four weeks of December 614 deaths were referred to the principal zymotic diseases in London; of these, 2 resulted from small-pox, 149 from measles, 59 from scarlet fever, 176 from diphtheria, 88 from whooping-cough, 94 from enteric fever, and 46 from diarrhoea. These 614 deaths were equal to an annual rate of 1·8 per 1000, against 1·6 in each of the preceding two months. No fatal case of any of these diseases was recorded last month in St. Olave Southwark; in the other sanitary areas they caused the lowest death-rates in St. George Hanover-square, Hampstead, St. Martin-in-the-Fields, Holborn, City of London, and St. George Southwark; and the highest rates in Fulham, St. James Westminster, Strand, Lime-

house, Battersea, Greenwich, Woolwich, and Plumstead. Only 2 fatal cases of small-pox were registered in London during the month under notice, the corrected average in the corresponding periods of the preceding ten years being 17; these two cases belonged to Marylebone sanitary area. The 149 deaths referred to measles were as many as 126 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Poplar, Greenwich, Lewisham, Woolwich, Lee, and Plumstead. The 59 fatal cases of scarlet fever were little more than half the corrected average number; this disease was proportionally most fatal in Fulham, Whitechapel, and Bermondsey sanitary areas. The 176 deaths from diphtheria exceeded by 30 the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Fulham, Westminster, St. George-in-the-East, Limehouse, Mile End Old Town, St. Saviour Southwark, Battersea, and Greenwich. The 88 fatal cases of whooping-cough were as many as 138 below the corrected average number; this disease was proportionally most fatal in St. Luke, Shoreditch, and Battersea sanitary areas. The 94 deaths referred to enteric fever were 31 above the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Hackney, Strand, Whitechapel, and Lewisham. The 46 fatal cases of diarrhoea were slightly below the corrected average number. In conclusion, it may be stated that the mortality in London during the month under notice from these principal zymotic diseases was no less than 30 per cent. below the average.

Infant mortality in London during December, measured by the proportion of deaths under one year of age to births registered, was equal to 140 per 1000, and was below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. George Hanover-square, Marylebone, Hampstead, Stoke Newington, Holborn, Clerkenwell, and St. Olave Southwark; and the highest rates in Kensington, St. Martin-in-the-Fields, St. Saviour Southwark, St. George Southwark, Battersea, Lewisham, and Woolwich.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-CAPTAIN DONSON has been posted to the North-Eastern district. Surgeon-Major O'Sullivan has arrived from Singapore. Surgeon-Major Pike has completed a tour of service in Ceylon and embarked for England. The following officers have embarked in the *Victoria* for a tour of service in India: Surgeon-Lieutenant-Colonel Ring, Surgeon-Captains Donnet and Sparkes, and Surgeon-Lieutenant More.

INDIA AND THE INDIAN MEDICAL SERVICES.

1st Bombay Grenadiers: Surgeon-Captain Street, officiating in medical charge, 7th Bombay Lancers, to the Medical Charge, vice Surgeon-Lieutenant-Colonel Wilkins, D.S.O., transferred. 21st Bombay Infantry: Surgeon-Lieutenant-Colonel Wilkins, in Medical Charge, 1st Bombay Grenadiers, to the Medical Charge, vice Surgeon-Major Burroughs, transferred to general duty at his own request. Surgeon-Major Rowney and Surgeon-Lieutenant Austen, just arrived from England, have been posted to general duty Bombay district temporarily. Surgeon-Lieutenant-Colonel Trevor, A.M.S., on arrival from England, has been appointed to the Medical Charge, Station Hospital, Kurrahee. Surgeon-Major W. G. H. Henderson has relinquished charge of the Hyderabad Prison, Surgeon-Captain J. Jackson assuming Charge of the Hyderabad Central Prison.

NAVAL MEDICAL SERVICES.

Surgeon A. G. Wildey has been appointed to the *Wildfire* (additional).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major William R. Smith to be Surgeon-Lieutenant-Colonel. Surgeon-Lieutenant David Todd, 1st Durham Volunteer Artillery (Western Division, Royal Artillery), to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 1st Fife-shire: Henry William Laing, M.D., to be Surgeon-Lieutenant. The Highland: Surgeon-Lieutenant-Colonel A. Sclanders, M.D., resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the Corps on his retirement. *Rifle*: 1st (Renfrewshire

Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders) : Surgeon-Lieutenant A. Peacock, M.B., resigns his commission.

THE JAPANESE ARMY MEDICAL SERVICE ORGANISATION AND ARRANGEMENTS.

According to the statement of eye witnesses published in the *Times* and the *Standard* there does not seem to be any doubt that the Japanese forces operating at Port Arthur were guilty of terrible atrocities after the capture of the forts and dockyard of that place. The conduct of the Japanese troops on that occasion has aroused a feeling of righteous indignation and disgust amongst even their well-wishers in Europe, which the Government of Japan will find it very difficult to remove. It shows that the civilisation of the Japanese is but veneer after all. Their intelligence, energy, and enterprise, and their remarkable aptitude in acquiring and applying the results of European science and art cannot, however, be denied. Their medical arrangements during the present war with China, and their hospital organisation at Hiroshima and elsewhere, in connexion with their Red Cross Society and the Army Medical Staff and Medical Staff Corps, seem to have been excellent. In the attack and capture of Port Arthur on Nov. 21st the main body of the attacking force of the Japanese army passed through a small hamlet which was afterwards used by the Japanese Red Cross as one of the chief sites of their advanced field hospital work. The wounded, the special correspondent of the *Standard* writes, were rapidly brought in from the front, placed on straw, and promptly attended to by members of the medical service. The equipment of the Japanese Red Cross is stated to have been excellent. There was a plentiful supply of antiseptic agents and dressings, and all the operations were conducted on the recognised principles of antiseptic surgery of Western civilisation. Labels were attached to the wounded briefly stating the nature of the injury and what had been done before the cases were transferred to the hospitals in the rear, and, in fact, everything was done in accordance with the principles and methods followed in modern war in Europe. The resistance offered by the Chinese was small and ineffective, and there was, no doubt, no great strain on the Japanese medical organisation and arrangements; still the work was well done and very creditable to the Japanese service. With the small total of casualties of 29 officers and men killed and 210 wounded, the Japanese managed to capture at Port Arthur sixteen forts and redoubts with all their guns, together with the dockyard with its plant and workshops complete.

THE WAZIRISTAN EXPEDITION.

The latest intelligence regarding the punitive expedition against the Waziris shows that, notwithstanding that the British force has destroyed or dismantled many fortified towers and met with relatively little opposition, the affair is not by any means at an end. The Waziris have fled, no doubt; but they will probably return before very long and again attempt to harass the troops by occasional raids and desultory attacks on positions occupied by the British force. In the meantime, what with the extreme cold and severity of the weather in the Afghan hills at this season and the difficulty of transport, all field operations are very trying to the troops concerned, and the amount of pulmonary disease among the native portion of the force especially will probably be considerable.

THE LATE CHOLERA OUTBREAK AT LUCKNOW.

We are glad to notice that the services rendered by the medical officers on the occasion of the late severe cholera outbreak in the Lucknow garrison have not only been handsomely acknowledged by Sir Robert Low, K.C.B., the general officer commanding the Oudh District, but that Sir George White, the Commander-in-Chief, has desired that his thanks may be conveyed to them, and that this may be noticed in their service sheets. His Excellency also expressed his admiration of the devotion of the wife of Colour-Sergeant Millett, 1st Battalion, East Lancashire Regiment, the corps, it will be remembered, that suffered so severely during the outbreak in question.

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on the 8th inst., Inspector-General F. W. Davis in the chair, the sum of £99 was distributed among the several applicants.

DEATH IN THE SERVICE.

Deputy-Inspector-General David Wilson (retired) died suddenly at his residence at Devonport on the 8th inst., in his sixty-seventh year. He was Fleet-Surgeon of the *Himalaya* in South Africa during the Zulu War in 1877-79.

The *Broad Arrow* states that the Secretary of State for India has refused to sanction the extension of the services of Surgeon-Major-General Bradshaw, P.M.O. with Her Majesty's Forces, as proposed by the Government of India. He will consequently be retired in March next on attaining the age of sixty-two.

Surgeon-Major-General William Arthur Thomson, M.B., has been appointed Honorary Physician to the Queen, vice Surgeon-General J. Fraser, M.D., C.B., deceased.

Brigade-Surgeon-Lieutenant-Colonel W. R. Hooper, who has been appointed to succeed Sir Joseph Fayrer as President of the Indian Office Medical Board, is the senior of his rank, and has held several important appointments in India. He entered the Indian Medical Service in 1859.

Correspondence.

"Audi alteram partem."

"THE CARE OF THE PHTHISICAL POOR."

To the Editors of THE LANCET.

SIRS,—That the progress of preventive medicine will always remain one of the distinctive features of the Victorian era has been shown by an abler pen than mine and with a mastery of detail to which I can lay no claim. Nevertheless, the leading article which appeared under the above title in the last issue of THE LANCET calls attention to a great question which, as you truly say, urgently presses for solution. It involves no reflection on existing institutions for the treatment of phthisis to point out that, in conformity with the design of their supporters and administrators, their chief use is to minister to the wants of acute and advanced cases. The subjects of pulmonary tuberculosis in its earlier stages are mostly consigned to the out-patient departments, attendance in which involves not only loss of wages and increasing penury, but leaves them to carry on a hopeless struggle against their relentless enemy under domestic conditions which combine to ensure its ultimate victory and enable it to claim fresh victims from among their susceptible offspring. The magnitude of the evil is attested by the fact to which you draw attention—namely, "that about one person out of every seven who die succumbs to phthisis." On the other hand, the evidence that that disease need not, in all cases, lead to a fatal issue is unequivocal. The late Dr. Hughes Bennett placed on record the fact that over 20 per cent. of the necropsies he had performed on patients who had died from non-tuberculous diseases or as the result of accident revealed the cicatrices of old pulmonary vomicae. Other pathologists have made similar and confirmatory observations. What, then, is being done to meet the requirements of such a situation? Having regard to the paucity and the nature of the hospital accommodation which is available for the abounding multitude of phthisical poor, it would not be far from the truth to say that practically nothing is done until in too many instances medical skill and hygienic surroundings can only avail to alleviate suffering and delay the inevitable issue. Provision for the treatment of the subjects of injuries and of acute disease and homes to expedite their convalescence abound. The great blot on our hospital system, the yawning gulf in our charitable and administrative organisations for the relief of disease, is that no effort has as yet been made to check in the early stages the ravages of a disease which claims a holocaust amounting to one-seventh of the total annual mortality. So glaring a defect is a reproach to an age which has witnessed the establishment and maintenance of a national system of vaccination and the devotion of public funds to such purposes as the treatment of the sick poor, the isolation of the contagious and the mentally unsound, and the disinfection of dwellings. The first step should be to provide in each sanitary district a bacteriological laboratory in which the sputa of suspected persons could be examined at the public expense on the request of the medical attendant; the

next, but more difficult because more costly, would be the erection of specially constructed buildings on carefully selected sites, to serve as temporary homes of rest and treatment for those who, in most of the existing institutions, would be treated as out-patients.

Is it too much to hope that the Victorian era will not close before something has been accomplished to meet what is, perhaps, our greatest national want?

I am, Sirs, yours faithfully,

Jan. 5th, 1895.

W. BEZLY THORNE.

"CHILD MORTALITY IN ENGLAND."

To the Editors of THE LANCET.

SIRS,—Mr. Biddle, in his letter on this subject in the last issue of THE LANCET, expresses the opinion that the late Dr. William Farr would have approved the use of his "coefficients" as "the best means of setting forth the relative mortality of the several age groups." Having for more than twenty-five years enjoyed the advantage of daily official intercourse with Dr. Farr, I feel justified in asserting that he would have entirely endorsed your unfavourable criticisms on Mr. Biddle's method and conclusions. It is true that Mr. Biddle's "coefficients" correctly show the relative mortality in any age group to the mean mortality at all ages; and it is also true that the mortality in the age group 0 to 5 now bears a higher proportion to this mean mortality than it did ten or fifteen years ago. Mr. Biddle argues and assumes from this that the power of resistance to disease and death among children at this age must therefore have declined during this period. This assertion is in direct opposition to the evidence afforded by the fairly steady decline in the annual death-rate per 1000 at this age period during the last thirty years, which beyond question implies that an increasing proportion of children born in this country now attain the age of five years. I cannot refrain from expressing surprise that Mr. Biddle, in spite of his long devotion to vital statistics, should fail to see that his "coefficients" are absolutely fallacious as a test of the increase or decrease of mortality in any given age group. Child mortality is, indeed, shown by Mr. Biddle's method to have increased, whereas by the unflinching test of the rate of mortality per 1000 living we know that it has considerably declined; and he has thus been led to make the indefensible assertion that the power of resistance among children to disease and death grows less year by year. It is unnecessary to discuss Mr. Biddle's precise method of obtaining his "coefficient" which has led him to make his unfounded assertion; but, knowing that it is the quotient obtained from the group death-rate and the mean or average death-rate at all ages, it is somewhat amusing to be told that, "having the average and the coefficient, we easily obtain the group death-rate as their product;" or, in other words, that we easily come back to the point whence we started. The true rate of increase or decrease in the mortality at any age group can only be obtained from the recorded death-rates among the persons living at the same ages in a series of years, and the use of the mean death-rate at all ages in Mr. Biddle's method introduces an inevitable source of fallacy. It may be, and indeed is, a matter for serious consideration and effort that child mortality is not decreasing at the same rate as the mortality of persons above the age of five years, but this fact gives no kind of warrant for Mr. Biddle's assertion, to which you were so fully justified in taking exception. Mr. Biddle misses or ignores the main point of the argument when he asserts, with regard to the increased proportion of child mortality to the mean mortality at all ages, that it makes no difference whether this is due to the increase of mortality among children or to the decrease of mortality at ages above five years. Allow me in conclusion to refer briefly to Mr. Biddle's line of argument as to the comparative power of resistance among London children to zymotic disease. Here again his "coefficients" appear to have led him to make fully as untrustworthy conclusions. He finds that the rate of mortality from scarlet fever, diphtheria, measles, whooping-cough, and diarrhoea, at the age group 0 to 5, now bears in each case a higher proportion to the mean death-rate from the same diseases at all ages, than was the case eighteen years ago. This fact is not without interest, but it affords no title of evidence of any increase or decrease of the power of resistance among children to these several diseases. The decline in the death-rate from scarlet fever during this period, for instance, is

one of the most remarkable facts in connexion with recent mortality statistics; and yet, because Mr. Biddle's "coefficient" for this disease shows an increase, he argues a decline in children's power of resistance to this disease. May not the fact upon which he bases this assumption be probably due to a decline in the virulence of the type of recent scarlet fever? We know that in severe epidemics of zymotic disease the deaths include a larger proportion of older children and adults than in non-epidemic periods; and yet Mr. Biddle sees in the decreased proportion of deaths from this disease above the age of five years a decreased power of resistance to the disease under that age. Again, because medical practitioners do not now so often as formerly assign diarrhoea as the cause of death of children and adults aged above five years, a decreased power of resistance to this complaint among children under this age is assumed!

I am, Sirs, yours faithfully,

Surliton, Jan. 7th, 1895.

NOEL A. HUMPHREYS.

. We regret that we can at present give no more space to this question.—ED. L.

"THE BARIUM WATERS OF LLANGAM-MARCH AND THE THERAPEUTICS OF BARIUM SALTS."

To the Editors of THE LANCET.

SIRS,—The use of the salts of barium have lately come under special notice in the columns of THE LANCET, and hence I venture to offer this small contribution to the subject. One of our most eminent physicians in Dublin, the late Dr. Alfred Hudson, fully thirty years ago taught me the value of iodide of barium in strumous glandular affections, and ever since I have used his formula with remarkably good results in suitable cases. Dr. Hudson's favourite prescription was as follows: R—Barii iodidi, gr. ii.; aquæ, 3 ii.; misce et solve. Deni adde: Syrupi ferri iodidi, ext. sarsæ comp. fl. aa 5i.; succi conii, 3vi.; one teaspoonful in half a wine-glassful of water thrice daily after food.

I am, Sirs, yours faithfully,

Dublin, Jan. 7th, 1895.

F. R. CRUISE, M.D. Dub.

THE PLURAL OF LOCUM TENENS.

To the Editors of THE LANCET.

SIRS—I fear that in the matter of the missing plural for locum tenens "purity of language" will ever want its avenging philologist. This technical but time-honoured use of the present participle singular as a substantive is itself a barbarous dog-Latinism, and cannot be purified by pluralisation. In default of any possible authority from philological sources I would suggest "*locum-tenents*" to serve as a practical plural for this singular solecism. This hybrid word should be spelled with an "e" in the fourth syllable instead of an "a" (as in the Anglo-French and familiar form of the word "tenant") in order to avoid confusion with other technical usages.

I am, Sirs, yours truly,

Jan. 4th, 1895.

H. B. DONKIN.

AMINOL AS A GERMICIDE.

To the Editors of THE LANCET.

SIRS,—The interesting remarks and speculations of Dr. Thorne Thorne at the recent meeting at the Examination Hall, in reference to finding "in the bodies of lower animals the medium by which specific contagia may be reduced to comparative or complete impotency" receive no little elucidation and support from what we know of "the amines process of sewage treatment" and the disinfectant aminol. The active principle in both these is a gas derived from herring brine (which contains blood and debris from the pickling of herrings) when acted upon by strong lime water. This gas is a most potent germicide and antitoxin and has by no means received the attention and study which it deserves. The proportion of herring brine used in sewage treatment, three grains to the gallon, is so small that "it would seem highly probable that this process results in the production (perhaps only in a very small amount) of a substance or substances strongly inimical to bacterial life. As a matter of fact, there is no valid chemical reason to be urged against such a conclusion."

¹ Brit. Med. Jour., Nov. 1st, 1890.

That this must be so is evidenced, amongst several other such cases, by the report on the experiments at Salford. For instance, Dr. Klein reports as follows: "Received on July 29th four samples, sealed 'The Amines Syndicate,' labeled—(1) Effluent, filtered, 3 P.M., July 27th, 1891; (2) Effluent, unfiltered, 1.30 P.M., July 27th, 1891; (3) River Irwell, above intake, 11 A.M., July 27th, 1891; (4) Pendleton sewage, 11 A.M., July 27th, 1891. Of each of these samples made two plate cultivations, using for each plate of No. 1 one cubic centimetre, No. 2 one cubic centimetre, No. 3 ten cubic millimetres, No. 4 one-hundred-thousandth of a cubic centimetre."

After one week's incubation the following was found:—Sample 1 (filtered effluent) contained innumerable colonies; except a dozen or so of largish white colonies all the others (uncountable) were of one kind, small, grey, liquefying; compared with Sample 2 I am of opinion that the filter has added to the effluent an uncountable number of bacteria of one and the same species. Sample 2 (unfiltered effluent) contained ten colonies, amongst them two moulds, for one whole cubic centimetre; therefore, only eight bacteria being present, it may justly be said that the effluent was practically sterile. Sample 3 contained on average 80 to 100 thousand bacteria per 1 c.c. Sample 4 contained above 10,000,000 per 1 c.c. Mr. Leo Taylor made daily bacteriological and microscopical examinations, the overflow effluent in all cases being practically sterile, whilst the sewages were teeming with countless organisms.

It would take far too much of your space to multiply examples, but it has been proved that lime alone will not do this; therefore we are driven back to the conclusion that from the refuse of lower animals (herrings) a germicide of great potency is evolved by lime. This sheds light on Dr. Thorne's remarks. Many medical men have used this compound in surgery and medicine during the last five years, and it has been found eminently useful in gonorrhoea, in diphtheria, in offensive discharges of all kinds, in dysentery as an injection, and in diarrhoea arising from animal poisons. In contradistinction, it is inert in diarrhoea arising from unripe fruit or mechanically irritating ingesta, which goes to show that the astringent action of the lime water is not the active agent. It forms a perfectly antiseptic surgical dressing.

Fish feed upon all the impurities which drain from the land into the sea, and if there be truth in the theory that by introducing these specific contagia into the bodies of lower animals we may find developed therein an antitoxin (as they themselves are uninjured) we should naturally look for it in their bodies. That is so, and this extraordinary poison to bacteria is evolved from the nervous system and roes of herrings by the action of lime. This substance, so inimical to bacteria, is perfectly innocent to human beings, and may be drunk, even in the form of sewage effluent, with impunity, though I should not advise this latter proceeding. Two swine were inoculated by Professor Brown with swine fever; one was left alone and died, the other was fed on lime water and herring brine and survived. In the first forty-nine weeks of this year 6932 pigs died from swine fever, 54,405 were killed as diseased, and 1250 slaughtered as suspected. It is more than probable that a few pounds would have saved this costly stock. I might multiply examples indefinitely, but what I wish to arrive at is this—that the remedy be tried by subcutaneous injection, and its results compared with Behring's antitoxin. If it turns out a success numbers of lives may be saved, much irritating and unseemly disputation may be avoided, and the way cleared to a final and convincing analysis of this gas and its employment in a known chemical form. I do not myself doubt the result.

I am, Sirs, your obedient servant,
H. CAMPBELL POPE, M.D. Lond., F.R.C.S.

Goldhawk-road, W., Dec. 17th, 1894.

THE ABUSE OF PROVIDENT DISPENSARIES.

To the Editors of THE LANCET.

SIRS,—Will you please insert in your next issue the following resolution, which was recently passed at a meeting of the medical practitioners of the West Salford Parliamentary division, held at the town hall, Pendleton? We venture to think that the action taken by the medical staff of the Pendleton Provident Dispensary in severing their connexion with the dispensary will meet with your support and the approval of the profession at large. The following

are some of the factors which have brought about the resignation of the medical staff. 1. This dispensary, in common with other provident dispensaries, has not fulfilled the purpose for which it was intended, the bulk of the members being well able to pay ordinary medical fees. 2. The absence of any wage limit or other standard by which the admissions can be regulated and the interests of the profession safeguarded. 3. Practically the whole management of the dispensary is in the hands of a lay committee, who only consider the financial success of the dispensary and who care nothing for the proper remuneration of the medical staff. 4. The remuneration bears no proportion to the labour and responsibility attached to the work. 5. Some of the branches of the Manchester and Salford Provident Dispensary have recently been guilty of a most objectionable form of professional advertising.

I am, Sirs, yours truly,

PHILIP GELL GARRETT,

Hon. Sec. to the meeting held on the 27th ult.

Albany-square, Pendleton, Jan. 1st, 1895.

Resolution.

Resolution carried at a meeting of medical practitioners held at Pendleton town-hall on Dec. 27th, 1894. Proposed by Dr. Fraser, seconded by Mr. Wolstenholme: "That the Manchester and Salford Provident Dispensary system, as at present conducted, is inimical to the interests of the profession, derogatory to its dignity, and unworthy of the countenance and support of medical men. That this meeting of medical practitioners residing in the West Parliamentary division of the borough of Salford desires, therefore, to record its firm conviction that the members of the staff of the Pendleton Provident Dispensary, in unanimously sending in their resignations, have consulted the best interests of the profession and deserve the thanks of all who value its present and future welfare."

POSTAL FACILITIES.

To the Editors of THE LANCET.

SIRS,—I am surprised to find how few of the public are aware of two postal facilities which the neighbours of a district post office enjoy, and for the benefit of my professional brethren I will mention them: (1) the right to hand a telegram, prepaid by stamps or coin, to any telegraph messenger who may pass, and thus save the inconvenience of despatching a servant to the office; (2) the power to post on Sunday up to 6 P.M. with an extra halfpenny stamp letters for the country, which then reach their destination on Monday morning. As I am afraid a good deal of arrears of correspondence is worked off on Sunday this is really a gain.

I am, Sirs, yours faithfully,

Jan. 8th, 1895.

CAVENDISH SQUARE.

A MISSING GUIDE.

To the Editors of THE LANCET.

SIRS,—With reference to the promised appearance of the Transactions of the International Medical Congress in April next, let us hope some sanguine expectations may be realised. What I should like to know is the probable date of issue of an exceptionally beautiful guide to Rome which was to have been issued to members at the opening of the Congress in March last. I was present during the whole of the Congress and I failed to feast my vision on that attractive production. Of all the disappointments of that memorable meeting the non-appearance of the guide-book was the greatest blow of all to

Yours faithfully,

Jan. 5th, 1895.

BIBLIOPHILE.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Magistrates and Prosecutions for Excessive Smoke Production.

ON Friday last a deputation representing the Manchester and Salford Sanitary Association and the Noxious Vapours' Abatement Association presented a memorial to the city justices at their annual meeting, suggesting that cases of prosecution for excessive smoke production should be heard by the stipendiary magistrate. It certainly seems an anomaly that the case of the accused should

be judged by one who is probably just as guilty as he is. Chemical manufacturers are frequent offenders and they are well represented on the magisterial bench. The deputation did not impute to the magistrates any unfairness or any attempt to screen each other. The position is, however, by some at least of them, felt as unpleasant, as it must be to those who are conscious that the judge and the accused might very well play Box and Cox between the bench and the dock.

Juvenile Offenders.

A second deputation waited on the magistrates from the Strangeways Refuge for Children, one of the most useful philanthropic institutions in Manchester, and submitted a resolution which had been passed by the committee suggesting that the time had come when charges against juvenile offenders other than criminal should be separately considered by the magistrates and no longer be included in the general business of the police-court. This proposition would commend itself to almost everyone, for exposure to moral contagion ought to be avoided where possible. A committee of the justices was appointed to consider the matter.

Boys' and Girls' Refuge and Home.

This institution, mentioned in the last paragraph, completed its twenty-fifth year of work last week. It owes its origin to the philanthropic zeal of Mr. Leonard K. Shaw, who is still as earnest as ever in seeking to help the poor waifs of this city. On Jan. 4th, 1870, Mr. Shaw and a few friends met to found the Boys' Refuge and Industrial Brigade, as it was then called, and from a very humble beginning a most important charitable agency has developed. The institution includes the central refuge in Strangeways, near to our Assize Courts, with workshops, six homes for little orphan boys and girls, working lads' institute, brigade boys' home, girls' training homes, seaside home at Lytham, emigration training homes, home for crippled and incurable children, open-all-night shelters, prevention of cruelty to children branches, industrial brigades, day nursery at Ancoats, a refuge depot and book saloon, and prison gate mission. There is a branch at Belleville in Canada, and boys are sent year by year to the training ship *Indefatigable*. During 1894 750 children have been under care and training in the refuge and branch homes; 107 children have been sent out to Canada, making the total number now in the colony over 900: ten boys have been trained on board the *Indefatigable*; 1511 boys have had a week's holiday under canvas at the camp at Birkdale, near Southport; and other good deeds almost innumerable have been done. The annual meeting was attended by the Lord Mayor and by many distinguished citizens of various political and religious views; for the institution and its practical, sensible management have attracted many well-wishers.

Jan. 8th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Medical Faculty at University College.

CIRCUMSTANCES prevented the opening address of Professor Gotch being given at University College at the commencement of the session. The classes have been well attended, and the medical school of Liverpool, which has now existed for more than half a century, is in a most flourishing state. Its success is due to the untiring and self-sacrificing services of present and past lecturers, for it is only of late that any of the chairs have been endowed, and even now only a few have this advantage. Granting all the advantages of metropolitan schools, it must be admitted that Liverpool occupies a very important place in the north of England and has all the material for affording a sound medical education to any student. Moreover, the facilities for acquiring a practical knowledge of any department of medicine or surgery are now so great that at least a part of the curriculum may be spent here with profit by any student.

Jan. 8th.

A MEETING of persons interested in the Midwives Bill was held on the 9th inst. at the Midwives' Institute and Trained Nurses' Club, 12, Buckingham-street, Strand.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Royal Infirmary.

THE annual report of the Edinburgh Royal Infirmary was submitted at a meeting of contributors on Monday last, Lord Provost McDonald occupying the chair. At the beginning of the year there were 663 patients in hospital, and during the year 9190 new cases had been admitted, making a total of 9853 treated during the year. Of this number 641 died in hospital. Over 4000 of the cases were medical, while there were more than 5000 surgical cases. Over 400 additional cases had been treated as compared with the preceding year. The largest number of patients in hospital at any time was 748, and the average time each patient had been in hospital was 22.6 days. Over 4000 of the cases treated were from the country. In the out-patient department 25,500 cases had received attention. The ordinary income had been £29,686, showing a diminution of £1083 compared with the preceding year, most of this being due to a falling off in the legacies and donations under £100. There is also noted a falling off in the amount of the church collections. There had been a diminution of £795 from employes at public works in the country, this being due to the prolonged strike of the workmen at collieries. The ordinary expenditure was £42,074, a decrease of £1857 on the figures of the preceding year. It is pointed out that the cost of maintenance per bed was 15s. 3d. less and the medical expenditure 14s. 1d. less than was the case the preceding year. The cost per annum of each occupied bed is reckoned at £58 10s. 4d. The extraordinary receipts for the year—i.e., of donations and legacies over £100—amounted to £22,376. As regards the convalescent home at Corstorphine, there had been 1450 admissions from the infirmary, the average daily number in the home being 79, and the average period of residence 20 days. The managers express their satisfaction at the work the infirmary is doing, but again draw attention to the need for increased accommodation, and as soon as the financial position of the country improves they propose to bring forward a scheme for its extension.

Annual Report of the University of Edinburgh.

During the past year the total number of matriculated students (including 140 women) was 2949. In the faculty of medicine there were 1494 students; of these, 622 belonged to Scotland, 498 were from England and Wales, 74 from Ireland, 59 from India, 205 from British colonies, and 35 from foreign countries. The report refers to the new lectureships in medicine, but, as we stated on a former occasion, these are simply new titles for the old assistants. A new departure has been made in the admission of women to degrees in medicine, provided they have obtained their medical education in extra-academical schools specially recognised by the University, and the framers of the report expect that many will avail themselves of the privilege. It is anticipated that the McEwan University Hall will be ready for the graduation ceremonial on Aug. 1st.

Health of Edinburgh.

It is satisfactory to note that only 4 fresh cases of small-pox were reported last week. There were 212 cases of measles and 49 of scarlet fever reported. Amongst the deaths are 2 cases of small-pox. No fresh cases of small-pox are reported in Leith.

The Decrease in the Number of Glasgow Medical Students.

The statement of the numbers of matriculated students at Glasgow University for the past six years shows a net diminution during that period of 200 in the candidates for medicine. The figures for Edinburgh University show a net diminution in medical students during the same period of 531. The figures do not, in the case of either university, include students enrolled in single classes or women. Perhaps a part of the above-noted marked falling off in the number of medical students is to be ascribed to the recent copious "ploughings" in the preliminary examinations; but more probably it is simply an indication of the expected ebb in the tide of candidates which was sure to follow the rush to begin study before 1892, when the five years' curriculum became obligatory, while some of it also may be due to the extension of medical schools south of the border.

Small-pox in Glasgow.

Small-pox has reappeared in Glasgow. Four cases have

been removed to hospital, and the family has been taken to the Isolation House and revaccinated. No fresh cases have appeared so far, and the source of infection has not been traced.

Aberdeen City Hospital.

For the past fifteen months alterations have been going on at the Aberdeen City Hospital. Two of the four pavilions have been extended so as to accommodate sixteen additional patients in each, and provision has been made for lavatories, medical officers' rooms, and nurses' rooms. The apparatus for mechanical heating and ventilation is in the basement floor of the administrative block. There are underground ducts from the various pavilions, and the warm air is driven out by Blackman fans. On the ground floor of the extension of the administrative block is a spacious kitchen fitted with the best system of cooking apparatus. Above the kitchen is a suite of nurses' bedrooms. The new block of offices, 145 ft. 6 in. by 96 ft. 6 in., has a large open court in the centre, and contains laundry accommodation with all the latest fittings and machinery. The block also contains stable, coach-house, lavatory, dirty and clean clothes room, disinfected clothes room, and boiler-house. A new mortuary and a second gatekeeper's lodge have also been built. These additions have cost £16,000, and the propriety of erecting a probationary block at an additional expense of £5000 or £6000 is being considered.

The Death-rate in Aberdeen.

The deaths in the city last year numbered 2480 being at the rate per annum of 18.84 per 1000 of estimated population. Whooping-cough was prevalent from February to June, and last month an extensive epidemic of measles commenced. The number of cases of measles reported last week was 246, against 393 for the previous week.

Jan. 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Action against a "Cancer Doctor."

At Waterford quarter sessions last week a man brought proceedings against a person described as a "cancer doctor," for having by unskilled and wrong treatment caused him to suffer great pain for several months, the defendant having promised to cure cancer in the plaintiff's hand. Some three years ago the plaintiff obtained advice from Dr. G. I. Mackesy as to the condition of his hand; cancer was diagnosed, and he was informed that to save his life the hand should be amputated at the wrist. He objected to the operation, and after some time went to Sir P. Dan's Hospital in Dublin, where Dr. Mackesy's opinion was confirmed. He returned to Waterford and placed himself under the treatment of the defendant, who was a pump-maker by trade, and who professed to cure cancer for money. The plaintiff was treated for seventeen weeks with plasters and powders, which caused great torture, and again consulted Dr. Mackesy, who found that the disease was spreading up the arm, and had to amputate above the elbow. Judge Fitzgerald, county court judge, in placing the facts before the jury, spoke strongly on the responsibility incurred by individuals undertaking to cure diseases without the necessary medical qualification, adding that they were liable, both civilly and criminally for their conduct. The jury found a verdict for the plaintiff for 17s. 6d., the money paid to defendant, the judge certifying for costs.

Death of Mr. Frederick Kirkpatrick, M.B., F.R.C.S. Irel., of Dublin

Mr. Kirkpatrick died at his residence, 9, Merrion-square, Dublin, on the 3rd inst., aged eighty-two years. Born in York-street, Dublin, in 1812, he was educated in Wexford and in the University of Dublin. He was apprenticed to Surgeon Byrne of Carlow, and afterwards to Surgeon Wilmot. He obtained the M.B. of the University of Dublin in 1837, and the Fellowship of the Royal College of Surgeons in Ireland in 1844. He was for many years visiting medical officer at the North Dublin Union Hospitals, and retired on superannuation. His contributions to medical literature included papers on Epidemic Ophthalmia and Diseases of the Bones and Joints, published in the *Dublin Journal of Medical Science*. He strongly advocated the use of potassa cum calce in diseased joints. The funeral took place on the 5th inst., and was largely attended. His remains

were interred in St George's burial-ground, Drumcondra. Among those who attended his funeral were the President, Vice-President, Secretary, Registrar, and Council of the Royal College of Surgeons in Ireland, of which he was President in 1872-73.

Health of Dublin.

During 1894 the death-rate was 2.7 below the average, and was the lowest on record. The zymotic death-rate was only 2 per 1000, and was 50 per cent. below the rate in the English towns. During the week ending the 5th inst. five deaths were recorded from small-pox, and one from beri-beri. Fifty-eight cases of small-pox were notified, as against 46 the previous week. There are now in the three small-pox hospitals in Dublin 301 cases of small-pox. A staff of fifty-eight men and women is now engaged in the conveyance of patients to hospital, in the disinfection of clothing and bedding, and in the disinfection, whitewashing, and cleansing of infected houses.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Obesity with Thyroid Extract.

The rapid loss of body weight attending the treatment of myxœdema with thyroid extract very naturally suggested the applicability of the same method of treatment to that *bête noire* of middle-aged men and the fair sex—obesity. Already Drs. Leichtenstern and Wendelstadt of the Augusta Hospital, Cologne, have observed a manifest diminution of *embonpoint* in twenty-two of twenty-five obese subjects after a course of treatment with fresh sheep's thyroid and thyroid tabloids. The good effects observed are ascribed to more active combustion of the accumulated fat rather than to the diuresis which is a marked feature of the initial stages of the treatment. It is said that the process is more rapid during the early part of the cure, the loss of weight diminishing gradually. The actual wasting observed varied in the different cases from 1 to 5 kilogrammes during the first week and from 1 kilo. 0.50 gm. to 9 kilo. 0.50 gm. after several weeks of the treatment. MM. Charrin and Roger¹ have succeeded in procuring notable emaciation in animals subjected to subcutaneous injections of thyroid juice (daily dose 50 centigr. to 75 centigr.). Experimentally employing the same method in Professor Bouchard's wards, M. Charrin gave an average of 1 gm. daily of thyroid juice (both subcutaneously and *par la voie stomacale*) to a woman affected with general adiposis, with more pronounced accumulation of fat at the junction of the limbs with the trunk. In three months her body weight fell from 133 kilo. to 115 kilo. The treatment was afterwards continued at intervals. During the periods of suspension of the treatment the weight remained stationary; but fell at the rate of from 50 gm. to 130 gm. a day when the extract was again administered. A maximum of emaciation appeared, however, to be reached in time. Analogous, although less marked, results were obtained in a second patient, whilst a third (all were women) case remained unaffected. A like disappointment was noted in several other instances. M. Charrin ascribes the inconstancy of results to the different natures of the obesity, to insufficiency of treatment, and in certain instances to the bad quality of the substance employed. It is only right to add that the patients experimented on were one and all free from symptoms of myxœdema.

The Antitoxin Treatment.

In my last letter I informed the readers of THE LANCET that the State had voted to the Institut Pasteur for anti-diphtheritic purposes the sum of 100,000 francs. This credit will be an annual one; only a fifth of the sum will be diverted from the purpose and allotted to the vaccination department of the Academy of Medicine. A stud of 130 or 140 horses is judged sufficient to supply the whole of France with an adequate amount of anti-diphtheritic serum, the entire cost, including preparation and postage of the tubes, being estimated at 180,000 francs (£7200) a year. Towards this the State allows a sum of 80,000 francs in order to secure the gratuitous distribution of serum to charitable institutions. The balance (100,000 francs) will, it is expected, be supplied by that section of the public who are able to buy the serum they require, and by towns and

¹ Société de Biologie, Dec. 29th, 1894.

departments, which will doubtless follow the example of the department of the Bouches-du-Rhône in providing for the maintenance of a certain number of horses (six in the case of the above-mentioned department). The keep of each horse per annum is computed at 1000 francs (£40). A town may then for this sum assure for itself a monthly provision of serum sufficing for 150 injections of 20 c.c. each, one horse supplying an average of three litres of serum *per mensem*. It is anticipated that towards the end of this month all the pharmacies, the hospitals, and official charitable institutions will be supplied with antitoxin by the Institut Pasteur. Notice is given that the most expeditious way to procure serum is for the medical attendant to telegraph to Dr. Roux at the Institute before 3.30 P.M. A tube is then posted before 4 o'clock.

The Health of Paris.

The sanitary condition of Paris is a subject that interests the whole civilised world, for who does not aspire to visit this bright city of pleasure? A honeymoon and a run over to Paris are indissolubly connected in the minds of most of the fairer portion of humanity, and other visits follow later in life. Unfortunately, the idea that this capital is a hotbed of typhoid fever, diphtheria and other horrors is ingrained in the average British mind, and not a glass of water is swallowed without misgivings as to the dire consequences that may result. Well, let my timid compatriots read the following table of the mortality and then take heart of grace:—

1880	...	55,706 deaths	...	25.37 per 1000.
1881	...	55,103	...	23.56
1882	...	56,851	...	25.33
1883	...	54,753	...	24.36
1884	...	55,059	...	24.42
1885	...	52,720	...	24.35
1886	...	55,110	...	24.33
1887	...	52,836	...	22.00
1888	...	51,230	...	22.00
1889	...	54,083	...	22.93
1890	...	54,566	...	22.80
1891	...	52,262	...	21.65
1892	...	54,536	...	22.47
1893	...	52,947	...	21.80
1894	...	48,145	...	(a mortality of probably less than 20 per 1000.)

Thus, there have been nearly 5000 fewer deaths during 1894 than during 1893. Calculating one death in ten cases treated, this means 50,000 patients less than in 1893. In the week ending Dec. 29th, 1894, there were registered 875 deaths, instead of 938 the preceding week, and 1020 the average for that month. There were only 5 deaths from typhoid fever (average 10), 5 from whooping-cough, 2 from scarlet fever (2 is the average), none from small-pox (average 4) or measles (average 9), and last, but not the least important, 5 from diphtheria, instead of 30, the average for December.

Thesis Writing at the Faculty of Medicine.

The number of theses for the M.D. degree "presented and sustained" before the Paris Faculty from Dec. 18th, 1798, to July 31st, 1894, reaches a grand total of 28,793. This gives an average of only 300 M.D.'s a year. Nowadays this average is more than doubled.

Jan. 8th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

A Sydney Professor's Salary.

In reply to questions recently asked in the Legislative Assembly of New South Wales, the Colonial Secretary stated that the total yearly salary received by Dr. T. P. Anderson Stuart amounted to £1777 9s. 6d., made up as follows: annual salary as President of the Board of Health, £489; as Professor of Physiology at the Sydney University, £900; lecture fees from students, £377 15s. 6d.; and examination fees, £10 10s. He received no salary as Medical Adviser to the Government. It was further stated that it was not true that owing to Dr. Stuart's connexion with the Government service a great portion of the work which previously attached to his position at the University has now to be performed by other persons; but it was true that Dr. Manning resigned the position of Medical Adviser

because he could not for want of time faithfully perform the duties attached to that office and to the position of Inspector-General of Insane as well, and that in consequence of such resignation Dr. Manning suffered a considerable loss of salary. In reply to a question as to the propriety of members of the Civil Service holding dual offices of this kind, it was stated that the subject was one requiring serious consideration, and would probably be dealt with after a full inquiry into the general state of the service.

Prevalence of Typhoid Fever and Diphtheria in New South Wales.

Notification of infectious diseases is not compulsory in New South Wales, nor have the health authorities any power to enforce isolation of such cases. The Board of Health only learns in a haphazard way, through the police, or by persons applying for medical aid, and through returns voluntarily furnished by the hospitals, that there are cases of infectious disease in certain districts, and then can only use moral suasion to induce patients to go into the hospitals, attached to which are properly equipped isolation wards. In many cases, however, when hospital accommodation is offered it is declined, and patients are treated in their own homes with no proper surveillance. There are indications that typhoid fever is likely to be prevalent and severe during the coming summer. In twenty-four hours four deaths from this disease occurred at Wyalong, fifteen cases were reported in the Pitt Town division of Wallsend, a great number have occurred at Greta and at Hinton, and the disease has also broken out at Milparinka. Diphtheria also seems to be prevalent in the country. The Government medical officer at Parkes has drawn the attention of the health authorities to the occurrence of the disease in that town, and it is also rife at Deniliquin and at Gulgong.

Medical Notes in Central Australia.

Dr. E. C. Stirling of Adelaide recently accompanied an exploring expedition to Central Australia, and has furnished to the *Intercolonial Quarterly Journal of Medicine and Surgery* some notes on matters of medical interest. Concerning the disease known as "barcos rot," a condition in which the slightest scratches or abrasions of the skin pass speedily into rapidly spreading, freely suppurating, yet superficial and painless ulcers, he says that it is probably due to several causes—infection by flies, the absence of fresh fruit and vegetables, and often of fresh meat, the sudden alternations of temperature, from 20° F. at night to 85° in the day during the winter, while the sores are continually subject to fresh irritation. The disease is popularly ascribed to scratches from the mulga wood (*Acacia aneura*), but, he thinks, without any reason. The best treatment is protection of the sores from irritation and the application of unguentum acidi borici. Dr. Stirling noticed that a large number of the aboriginals, male and female, young and adult, presented a peculiar conformation of the tibia, which were curved anteriorly and were laterally flattened. He did not discover any associated pathological conditions, and is unable to determine whether the abnormality is to be regarded as a racial characteristic or a pathological condition. Circumcision and subincision were performed by all the natives met with, and he could find no support for the view that subincision, or splitting the urethra from the meatus to the scrotum, is done to prevent procreation, and heard of well-authenticated instances of three, four, or even five children in a family who were the offspring of subincised males. Little information could be obtained regarding therapeutic agents employed by the natives. Inunction with grease and red ochre is used in nearly every complaint. In some extreme cases freshly drawn blood is administered internally, and recently passed urine is used as an antidote to strychnine. Dr. Stirling saw several dogs and one woman who had recovered after having swallowed doses of strychnine that usually prove fatal. Probably the remedy acts as an emetic.

Beri-beri in New South Wales.

Dr. R. T. Paton, Government Medical Officer, Sydney, contributes to the *Australasian Medical Gazette* of November a paper with the above title. He mentions several cases of peripheral neuritis in Chinamen which he regards as true beri-beri. One case proved fatal from implication of the cardiac and respiratory branches of the vagus, and a post-mortem examination was obtained. The heart was large and pale, but not fatty, and the limbs, though apparently cedematous, contained no serous effusion. The patient was

one of six living in a cabinet-maker's shop, all affected with the disease. When he was removed to hospital he improved, but he returned to the infected building and again suffered from the disease.

Actinomycosis Hominis.

A case of actinomycosis of the thigh of a male aged thirty-five is reported by Dr. Marten of Adelaide. It caused an ill-defined swelling near the great trochanter, and was associated with weakness, fever, night sweats, and insomnia. The swelling was incised, and "gave exit to bloody fluid in which were hundreds of small, rounded, greyish, yellow-looking bodies, rather smaller than mustard seeds." These were examined and proved to be the ray fungus. Nodules continued to discharge from the wound and swelling occurred lower down. An incision was then made almost the whole length of the thigh, and various sinuses scraped out with Barker's scoop douche and irrigated with iodine solution. A portion of the vastus externus muscle, which was thickly studded with nodules, was excised.

A Case of Enlargement of the Liver and Jaundice, associated with the Passage of Hydatid Cysts by the Bowel.

At the last meeting of the Medical Society of Victoria Mr. J. P. Ryan read notes of a patient attacked with Jaundice, and presenting marked Enlargement of the Liver. After free purging a number of hydatid cysts were passed in the stools, and the jaundice and other symptoms disappeared. Five months afterwards he again became ill with jaundice, emaciation, and fever. The abdomen was opened and the liver examined with the hand, but no cyst discovered. The liver was freely explored with a long trocar, but neither hydatid fluid nor pus was withdrawn. The patient gradually developed chronic septicæmia, and died six weeks after the operation. At the necropsy the liver was found riddled with small abscesses, but no hydatids were found in any of the organs.

Melbourne Hospital Sunday Fund.

The annual meeting of the Hospital Sunday and Saturday Fund was held on Sept. 6th last. The report of the committee stated that the total amount received was £5794 16s. 7d., which is less by £1444 17s. 4d. than the preceding year. It was resolved that the medical charities to be assisted from the fund be the Melbourne Hospital, Alfred Hospital, St. Vincent's Hospital, Women's Hospital, Hospital for Sick Children, Eye and Ear Hospital, Homœopathic Hospital, Austin Hospital for Incurables, Benevolent Asylum, Immigrants' Aid Society, Collingwood Free Dispensary, Richmond Free Dispensary, Convalescent Home for Women, Convalescent Home for Men, Consumptive Sanatorium, and the Melbourne District Nursing Society.

The Bay View Asylum, Sydney.

In consequence of the charges made against the management of the Bay View Asylum, Sydney (to which reference has been made in a former communication), a Royal Commission has been appointed to make investigation, and has commenced taking evidence. The Commission has refused to allow Dr. Vause, the proprietor of the asylum, to be represented by counsel; but he will have the opportunity of questioning witnesses.

Hospital Appointments.

Dr. G. E. Rennie of College-street, Sydney, has been appointed Honorary Assistant Physician, and Mr. J. F. McAllister of Stanmore, Honorary Assistant Surgeon to the Prince Alfred Hospital, Sydney. Dr. E. H. Snibley has been appointed Honorary Anæsthetist to the Melbourne Hospital.

LITERARY INTELLIGENCE.—The publication of Mr. Hutchinson's "Archives of Surgery," which has lapsed for six months, is now being resumed. No. 21 will appear in a few days, with additional letterpress as well as nine plates; and this number, which commences Volume VI., contains a Chronology of Medicine from the Fifteenth to the Nineteenth Century. The publishers will in future be Messrs. West, Newman, and Co., 54, Hatton-garden.—The immediate appearance is announced of a French translation of the excellent work by Professor Zuckerkandl, Professor of Anatomy in the University of Vienna, on the Nose and Nasal Fossæ. The translation has been made by Dr. Lichtwitz of Vienna and Dr. P. Garnault of Paris from the second edition of Professor Zuckerkandl's work, and will be published by M. G. Masson, 120, Boulevard St. Germain, Paris, at the price of 40f.

Obituary.

EDMUND CHARLES JOHNSON, F.R.C.S. ENG., J.P., D.L.

WE regret to announce the death of Mr. Edmund Charles Johnson, which took place on the 3rd inst. at his residence in Eaton-place. The deceased gentleman, who long ago relinquished the practice of his profession, held an almost unique position in connexion with the furtherance of schemes for improving the condition of the blind and the deaf and dumb. He studied medicine at St. George's Hospital, to which his brother, Henry Charles Johnson, was for many years surgeon. After an exceptionally successful student career he qualified as M.R.C.S. in 1843, and then settled in Arlington-street, intending to follow obstetric practice. He had already as a student attracted the attention of Dr. Robert Lee, the celebrated obstetric physician of St. George's Hospital, to whom he was warmly attached, and who publicly acknowledged the value of the services rendered by him in the reporting of lectures and in the cataloguing of the pathological preparations which are now at Cambridge. He had not long been qualified to practise when, at the age of twenty-two, he went to Italy to attend on Viscount Cranborne, who suffered from the misfortune of blindness. In company with this nobleman, who was the eldest brother of the present Marquis of Salisbury, he visited the principal blind schools of Europe, and travelled extensively in Russia before the introduction of railways. On returning to England he definitely retired from practice, and until Lord Cranborne's death he devoted himself entirely to the care of his distinguished patron and friend. Owing to Lord Cranborne's affliction Mr. Johnson was led to take an active interest in all questions affecting the welfare of persons suffering from blindness, and his position with respect to that influential family greatly facilitated the prosecution of his object.

In 1850 the degree of "M.D. Lambeth" was conferred on him by the Archbishop of Canterbury, an honorary (if somewhat anomalous) distinction which does not entitle the graduate to practise medicine, and in 1858 he became a Fellow of the Royal College of Surgeons of England. The governors of the School for the Indigent Blind, Southwark, made him their vice-president and chairman, and in 1855 Her Majesty the Queen appointed him a member of the Royal Commission on the Blind and Deaf and Dumb, in which capacity he visited many of the Continental institutions for the blind. He also wrote a report on the Apparatus and Methods used in the Instruction of the Blind, which was presented to both Houses of Parliament. He was on the managing body of several institutions and associations for promoting the welfare of the blind, as well as the vice-president of the Congress for the Blind held in Paris in 1878. The French Government created him Officier d'Académie Française in 1882. He was the writer of numerous memoirs and official reports connected with his special subject, and a member of various learned societies in France, Italy, and Switzerland. He was made Deputy-Lieutenant for the Tower Hamlets in 1858 and J.P. for Middlesex and London in 1865. He attended actively to the discharge of his duties as a magistrate, and in his public capacity as well as in private life he invariably showed himself to be an intelligent and benevolent gentleman.

ARTHUR SUTHERLAND, M.B., C.M. GLASG.

MUCH regret has been occasioned in Ross-shire by the announcement of the death of Dr. Sutherland of Invergordon in that county. Although he was only in his fifty-second year his health had for a considerable time been seriously impaired; pneumonia ultimately developed, and his sufferings were brought to a close in the last week of 1894. His early studies were arranged on the expectation that he would follow the scholastic profession, as he, in fact, did for a time, but before long his thoughts became fixed on a medical career. Having completed the educational course at Glasgow University, he graduated as M.B., C.M., in 1869, and ultimately settled in practice in Invergordon, his native place. His selection of the medical profession was probably influenced by his fondness for biological science, especially botany and the natural history of marine animals and plants.

These pursuits, together with archæology, were the welcome occupation of his leisure hours, and provided him with subjects for interesting contributions to periodical literature. In addition to his literary and scientific attainments he possessed considerable artistic talent, being a skilful painter and the writer of many poetical pieces which well deserve publication in a collected form. His death is deeply lamented by the numerous friends to whom he was endeared by his genial manner and estimable character.

THE INDIAN MEDICAL CONGRESS.

THE Congress came to a conclusion on Dec. 29th, 1894.

The most practical outcome of its work that has as yet occurred is the answer given to a deputation to the Member of the Indian Council in charge of the Home Department (Sir Anthony Patrick MacDonnell, K.C.S.I.), urging that Government should give practical assistance to scientific research and sanitary development. Sir A. P. MacDonnell consented to advise the Government to accede to the request of the representatives of the Medical Congress.

Calcutta at this season of the year enjoys one of the finest climates in the world, and we make no doubt that, proverbial as that city is for its hospitality and festivities, the members attending the Calcutta Medical Congress have had a most enjoyable time. The gathering from all parts of India has been large, and we may be sure that those representatives of medical science from this kingdom, our colonies, and from the continent of Europe, who have seized the occasion of this Congress as an opportunity for turning their backs for a time on Western civilisation and their faces to that of the East, have been made thoroughly welcome.

THE SECTIONS.

MEDICINE.

The Natural Conditions affecting Cholera Spread in India.

Surgeon-Captain H. HERBERT, F.R.C.S., read a paper on Some of the Natural Conditions affecting Cholera Spread in India. In this paper he said: "I wish to touch on one or two points in the meteorology of cholera which I have imperfectly dealt with elsewhere.

"*Endemic areas.*—I have already published reasons for believing that cholera is very generally endemic in some degree throughout the greater part of India. Allowances must be made for imperfections in the registers both of the weather variations and of cholera intensity. This being granted, a relation between meteorology and the disease, such as I have shown for the Bombay Province, may almost be held to prove general endemicity throughout the province. The proportion between meteorological influence and cholera mortality is very fairly exact, and after complete epidemic subsidence the disease inevitably reappears as soon as the natural conditions become favourable, and in the history of its spread the influence of contagion is very lightly felt. In dealing with provinces as units I have classed the Punjab as non-endemic. This is not absolutely correct, for the disease is undoubtedly very mildly endemic in the eastern districts of the province; but all the severe visitations have been due to imported infection spreading from Hurdwar fairs. With limited time and material at my disposal I am sorry to say I have been able to make nothing of the natural conditions influencing cholera spread through the Gangetic plains; but the constant presence of the disease in some degree throughout the year, and the comparatively slight variation in annual cholera mortality, indicate that the disease is at least as endemic there as in the Bombay Province. It is inevitable that cholera infection must be exported from Lower Bengal more freely through the less endemic Gangetic plains than the perhaps feeble virus can be imported thence into Lower Bengal; but the bulk and extent of this travelling westward from the delta of the Ganges have been exaggerated, largely through the influence of Bryden's teaching. There must

always be the *appearance* of movement westward in the cholera epidemics of Northern India. For the chief cholera season comes early, in the hot weather, in waterlogged Lower Bengal. It is delayed as one goes westward with the diminishing annual rainfall, until in the Punjab ordinary epidemics come 'during and towards the end of the rains.' The monsoon, itself advancing from the east, blotting out the disease over the lower country and bringing the necessary rain for prevalence in the more western tracts, adds slightly to the appearance of travel in epidemics. And there is still another factor, which I have alluded to in treating of cholera in Berar. Suppose there are two consecutive years favourable to cholera prevalence throughout Northern India. In the first year the mortality in the lower Gangetic plains will be much heavier than in the Punjab. In the following year these eastern districts will feel to some extent the effect of exhaustion of material, of susceptible persons, and the mortality will hence be less; but in the west this will not be felt to any appreciable degree, and the fatality will be unchecked. Thus there will result a false appearance of motion in the two cholera epidemics. The so-called epidemic influence will seem to have concentrated itself more to the westward in the second year. In a recent number of THE LANCET there is a reference to two types of cholera outbreak; the one attaining its maximum at once, the other rising gradually. Is not the former typical of an importation from without, under conditions unsuited to the continued development of the organism; and the latter characteristic of multiplication of the indigenous organism under increasingly favourable natural conditions?

"*Rainfall.*—It is now, I suppose, generally accepted that large epidemics of cholera are mainly water-borne, infected individuals, infected clothing, and the like serving chiefly as links of connexion between the various water-supplies. It is even probable that wherever the disease is endemic the organism has a permanent existence in some of the people's water-supplies. Unless this be so, it is difficult to see how a water-borne epidemic can make its appearance in a place during the dry season, after perhaps a long interval of complete absence, without importation. Constantly repeated observation of instances of this led to the old belief in India that the disease must be air-borne, and not due to infection in any way. Thus it may almost be assumed that the weather elements influence cholera prevalence mainly through their effect on the water-supplies. I believe that meteorological influence on cholera is threefold. As might be expected, rainfall comes first in importance, temperature perhaps next, and atmospheric pressure last. The evidence¹ regarding rainfall and its effect on cholera which was brought forward in a paper submitted to the International Congress of Hygiene and Demography at Budapest pointed roughly in the following directions. The provinces of continuously high ground water level have cholera all the year round. Here the rains flood the tanks and wells, and lower the cholera-rate apparently by diluting the specific poison in them; and the heaviest cholera mortality is attained when the tanks are at their lowest. On the other hand, in the provinces of scanty rainfall and low water level it is found that the conditions most favourable to cholera spread are departed from in the other direction. Cholera comes in the rainy season and disappears in the dry seasons. A very low ground water level completely abolishes cholera prevalence. It appears likely that the observation of the Sanitary Commissioner to the Government of India on the cholera at Bellary in the drought of 1877 will be found to apply to other parts of India and at all times. It was noticed that the point at which the want of rain began to lower the cholera-rate was when the tanks and streams began to dry up, driving the people to the use of well water, then at a considerable depth. From all this it would appear that the most dangerous water to use in cholera times is tank or other surface water when the water has run very low. Why should water deep below the surface be unsuited to cholera development? The water is probably purer; but the comma bacillus is said to live longer in pure than in foul water, and deep wells in India are but little less liable to specific contamination than shallow wells are. For there can be little doubt that Indian wells become contaminated by cholera discharges, not so much by soakage through the soil baked hard by the sun in the

¹ The evidence related only to very broad tracts of country. The test of local experience is now required.

dry seasons, but rather directly by the washing of infected clothing on their margins and by the introduction of contaminated vessels into their waters. One obvious explanation of the unsuitability of deep well water for cholera growth is, as I have said elsewhere, to be found in its lower temperature, its removal from the influence of the sun's rays. On the other hand, one cannot help thinking that there is something more than this, and that the habits of the people in connexion with tank and river water have something to do with the development of the cholera organism in it. As already stated, it is not when the tanks are filled and overflowing that they are dangerous, but when their water runs low; when the number of people using them is greatest in proportion to the quantity of water available; when they become foul, not from the introduction of sewage, but from the bathing of men and animals, the washing of clothing, and as a result the constant stirring up of the mud from the bottom. That the number of persons using a water-supply in this way, both as a bathing ground and for drinking purposes, has something to do with the risk of cholera spread from it is borne out by the history of Hardwar fair epidemics.

"*Hardwar fair epidemics.*—Experience has shown that the element of greatest danger at these gatherings is the increase in numbers at Kumbh fairs. Two of the last three

Kumbh fair of 1891 was proclaimed as a triumph of sanitary skill, and due to the very exceptional sanitary arrangements in force. But it is not at all certain that an epidemic would have broken out had there been no special precautions taken. There was no outbreak at the Kumbh fair of 1855, and the assembly in 1891 was scarcely larger than at the Adh Kumbh fair of 1885, when there was no cholera, though no extraordinary precautions seem to have been taken. In both of these years 1885 and 1891 the water in the river was probably above the average (see appended table). On the other hand, at the Kumbh fairs of 1867 and 1879, when cholera did break out, the river was probably lower than the average; in 1879 probably well below it. In 1867 the crowd of pilgrims was so great that it would probably have counterbalanced a moderate excess of water in the river. There was one other feature in the weather of 1892 which may have helped in the spread of cholera. The hot weather was one of the earliest and most intense on record. But there have been other very hot years and no cholera. (1880 was the next hottest year. See column three in the table for reason why there was no cholera.) The practical inference to be drawn from all this is that the one sanitary need at these fairs for the prevention of general cholera outbreak is the adoption of measures to secure a rapid and free current of water past the

Table to show the Relation between Hardwar Fair Epidemics and the State of the River Ganges as it may be judged from the Government of India Weather Reports.

Year.	Attendance of pilgrims at the fairs.	Records of Himalayan snowfall and of cold weather rainfall on the Northern plains.	Result.
1867	Kumbh Fair, 1,250,000 pilgrims.	"In the cold weather (six months) 1865-67 the rainfall of the Punjab was only 44 per cent. of the average, and of the North-West Provinces 67 per cent. of the average" ("Bellew's History of Cholera," pp. 416 and 505). No record of snowfall.	Very severe epidemic. Registered Punjab cholera mortality, 43,146. "Probably greatly underestimated" (Sanitary Report for 1892, p. 141).
1879	Kumbh Fair, 500,000 pilgrims.	"The first striking peculiarity, at the beginning of the year, was the dryness of the atmosphere of Upper India, and the absence of the usual winter rains" (Sanitary Report for 1879, p. 156). "It was probably in consequence of the prevailing absence of rain, not only in January, but also in the two preceding months of 1878, that the temperature of Upper India was excessive and especially at Leb and the other Himalayan hill stations" (Meteorological Report for 1879, p. 160).	Epidemic. Registered Punjab cholera mortality, 26,125.
1880	Ordinary year.	The Commissioner of Kumaon reported with respect to the hills around the Upper Ganges Valley:—"The winter has been an exceedingly severe one. Snow fell at places where it was seldom seen" (Meteorological Report for 1880, p. 166).	Nil.
1885	Adh Kumbh Fair, 262,621 pilgrims.	"The rainfall of the year has furnished a very striking corroborative instance of heavy winter and late spring snowfall on the North-Western and Western mountain tract being followed by" (Meteorological Report for 1885, p. 195).	Nil.
1891	Kumbh Fair, 269,345 pilgrims.	"The cold weather was characterised by excessive snowfall in the Himalayas" ("Weather Review" for 1891, p. 476). "The cold weather rainfall the heaviest on record in many parts of upper India" ("Weather Review" for 1892, p. 529).	Nil.
1892	Ordinary year, 700,000 pilgrims.	"The cold weather was exceptionally dry. The snowfall on the hills was one of the lightest on record" ("Weather Review" for 1892, p. 529).	Severe epidemic. Registered Punjab cholera mortality, 75,959.

epidemics have fallen on Kumbh fairs; and as regards the origin of the third of these epidemics the explanation of the Sanitary Commissioner to the Punjab is of interest here. Comparatively few pilgrims had assembled; but it was one of the hottest and driest years on record in Northern India. The Sanitary Commissioner states: "In the submontane tracts many of the streams were dried up. The sanitary arrangements at the fair were those which proved so successful in 1891; it was impossible, however, to keep the water in the bathing pool so fresh as on the former occasion on account of the smaller volume of water in the river and the direct obstruction to its flow in the sacred pool by recently formed obstacles and foreshores." Thus each of the three epidemics was characterised by one feature—excess in the proportion of bathers to the quantity of water available, due in two instances mainly to increase in the number of pilgrims, and in the third to one of the driest seasons on record. And it may be shown as probable that they had no other effective condition in common, and that the fairs of other years did not possess this characteristic. I have no record of the condition of the river in different years but it may be judged very fairly from the records of Himalayan snowfall and of the cold weather rainfall on the northern plains. The exemption from cholera attack of the

bathing ghāt in dry years. There is not time to inquire whether a cholera outbreak here be due to relatively large specific pollution of the water or to the condition of the water rendering it a good culture medium. For several reasons I believe the latter to be correct.

"*Atmospheric temperature and pressure.*—Only a few words can be added under these heads. These two meteorological elements are, in a sense, antagonistic in their influence on cholera. Both high temperature and high barometric pressure are favourable to cholera prevalence. But a high temperature lowers the barometric pressure, consequently the pressure influence is not seen in the regular seasonal cholera changes, and even the effects of the variations from normal of atmospheric pressure are only well seen in parts of India where the temperature anomalies are small. The effect of temperature on the cholera organism is best judged in places where the water-supply is from wells. In tanks the result is complicated by the effect of shrinkage in volume of the water. As regards atmospheric pressure, it is interesting to notice that Hardie, in Queensland, has found the same relation between pressure and typhoid fever as I have in Bombay between pressure and cholera. He states 'that, although the period of highest barometric pressure—winter—

¹ Government of India Sanitary Report for 1892.

² Hardie's Atmospheric Pathology of Queensland, p. 101.

corresponds fairly with the period of lowest mortality, the higher the barometer during any season of the year the greater will be the death-rate."

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated at a meeting of the examiners on Monday, Jan. 7th, 1895:—

Anatomy and Physiology.—Henri Oscar Pomme de Mirimonde, Yorkshire College, Leeds; Nicholas Joseph Kendal, Wilfrid Anthony Legh Jackson, and John Charles Young, Mason College, Birmingham; Frederick Thomas Butler, Robert Hughes, Harry Melville Rees, William Harle Stott, and Fred Schofield Rhodes, Owens College, Manchester; Ernest Symes, and George William Bertram Beverly, University College, Bristol; David Richard Edwards, Charles J. Lintou Palmer, and William Daley, University College, Liverpool; Richard Rothwell Horley, Middlesex Hospital; and James Templeton, St. Mary's Hospital.

Anatomy only.—Langford Newman Lloyd, Charing-cross Hospital; Hubert Richard Rice, Mason College, Birmingham, and London Hospital; Charles Durban Ingle, University College, Bristol; Thomas Preston Yates, Owens College, Manchester; and Sidney Herbert Longhurst, Guy's Hospital.

Physiology only.—Arthur Cubley, Firth College, Sheffield, and Mr. Cooke's School of Anatomy and Physiology; Frederick Charles Torbitt, Owens College, Manchester; Alexander Evans, St. Mungo's College, Glasgow; George Henry Heron, University College, Liverpool; Jeffrey Golt, King's College, London; John Benjamin Augustus Treusch, Guy's Hospital; and Maurice Clare Bielefeld Anderson, St. Mary's Hospital.

Thirteen gentlemen were referred in both subjects, and five in anatomy only.

Tuesday, Jan. 8th:—

Anatomy and Physiology.—William Quinton Brown, William Richard Flint, and Charles Hilton Furnivall, St. Mary's Hospital; Edward Halford Ross, Ernest Lionel Forward, William Somerset Maugham, and Herbert S. Edgecombe Williams, St. Thomas's Hospital; Richard Galway Murray, St. George's Hospital; Josiah Oldfield, George Arthur Whitworth Spear, and Harold John Hutchens, St. Bartholomew's Hospital; Thomas Alexander Dowse, Charing-cross Hospital; George Quintin Richardson, Adelaide Hospital and Royal University, Dublin; Arthur Ernest Gilmore and Stanley Edward Denyer, Cambridge University; Francis John Nicholls and Robert Bidderston, Guy's Hospital.

Passed in Anatomy only.—Donald Ackland and John Herbert Crangle Fegan, Charing-cross Hospital; Frank Voller, St. Thomas's Hospital; Robert Douglas Dobie, King's College, London; and Thomas Hill Bailey, King's College, London, and Mr. Cooke's School of Anatomy and Physiology.

Passed in Physiology only.—Sydney Herbert Mason and Cyril Cecil Poole, Guy's Hospital; George Fernandez Mitchell Clarke, Charing-cross Hospital; Charles Nugent Chadborn, St. George's Hospital; and Emilio Frederico Crabtree, St. Bartholomew's Hospital.

Eleven gentlemen were referred in both subjects, five in anatomy, and five in physiology.

Wednesday, Jan. 9th:—

Passed in Anatomy and Physiology.—Henry Arthur Clifton Harris and Arthur Charles Haslam, St. Thomas's Hospital; Gordon O'Neill, Charing-cross Hospital; Basil Fenton Wingate, St. Mary's Hospital; John Basil Walters, James George Watt, and Charles Clifford Worts, Guy's Hospital; Frank Brickwell, William Beckton, and Ernest George Klunpp, St. Bartholomew's Hospital; Alfred Sigismund Bruzand and Herbert James Bryan, London Hospital; and Hewlett Breton, St. George's Hospital.

Passed in Anatomy only.—Austin Romuald O'Flahertie, Queen's College, Cork, and London Hospital; Charles Arthur Craven Salmon, Guy's Hospital; Francis Augustus Pitts-Tucker, St. Thomas's Hospital; and Colville Smith Agnew, Charing-cross Hospital and Mr. Cooke's School of Anatomy and Physiology.

Passed in Physiology only.—Robert Lendon Argles, St. Mary's Hospital; Alfred John Andrew, St. Bartholomew's Hospital; and Arthur Ernest Malaher, St. Thomas's Hospital.

Sixteen gentlemen were referred in both subjects, six in Anatomy only, and four in Physiology only.

SOCIETY OF APOTHECARIES OF LONDON.—At the recent Primary Examination (Part II.) the following candidates passed in the subjects indicated:—

Anatomy and Physiology.—C. S. Agnew, Charing-cross Hospital; W. Amsden, St. Bartholomew's Hospital; E. Brice, Birmingham; E. F. Crabtree, St. Bartholomew's Hospital; E. F. Dowling, St. Thomas's Hospital; W. H. Gale, St. Thomas's Hospital; A. H. Gibson, St. Thomas's Hospital; A. T. Griffiths, Birmingham; H. W. Hues, Birmingham; T. J. Hughes, Middlesex Hospital; W. J. Lindsay, Guy's Hospital; M. Paine, Women's Medical College; C. C. Poole, Guy's Hospital; E. W. W. Pugh, Birmingham; C. B. Salway, St. Thomas's Hospital; H. E. Scowercott, Cambridge; E. Whalley, Leeds; A. M. St. J. Wright, Madras; L. Wright, St. Thomas's Hospital.

Anatomy.—T. H. Bailey, King's College Hospital; P. Cator, St. Bartholomew's Hospital; C. F. W. Dunn, Cambridge; A. H. Fitzgibbon, St. Bartholomew's Hospital; C. F. Eddowes, St. George's Hospital; J. G. Gowlan, St. George's Hospital; M. B. Hebron, King's College Hospital; H. M. Maitland, Women's Medical

College; S. J. Meredith, Birmingham; A. Ross, Guy's Hospital; J. Scarr, Manchester; and A. M. Williams, Women's Medical College.

Physiology.—G. F. M. Clarke, Charing-cross Hospital; J. Freeman, University College, Bristol; J. R. Jeaffreson, St. Bartholomew's Hospital; F. T. Knott, Guy's Hospital; H. M. Waller, St. Bartholomew's Hospital.

The following candidates passed at the recent Primary Examination (Part I.) in the subjects indicated:—

Chemistry, Materia Medica, Botany, and Pharmacy.—H. M. Hardy, South London School of Pharmacy.

Chemistry, Materia Medica, and Pharmacy.—L. Eadstock, Birmingham; C. H. F. Dalton, Charing-cross Hospital; and A. G. Lang, Guy's Hospital.

Materia Medica and Pharmacy.—C. F. Eddowes, St. George's Hospital; and A. C. McLean, King's College.

Materia Medica.—W. O. Piper, Westminster Hospital.

Biology.—S. K. K. Haslam and E. C. Scarlett, Women's Medical College.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:*

Dr. Otto Heubner has been promoted to the rank of Ordinary Professor of Children's Diseases.—*Gratz:* Drs. von Steinbuechel and Rossa have been recognised as *privat-docenten* in Midwifery and Gynecology.—*Lyons:* Dr. Nové Jesserand has been appointed by competition Surgeon to the Hospitals.—*Marburg:* Dr. Finkler of Bonn has declined the chair of Hygiene.—*Odessa:* Dr. Medvedeff of St. Petersburg has been appointed to the chair of Zoology and Comparative Anatomy and Physiology.

LONDON POST-GRADUATE COURSE.—The Vacation Courses in Pathology and Hygiene will commence on Monday, Jan. 21st, and be given daily until Friday, Feb. 1st. This will enable practitioners who can spare twelve days to study those subjects to compress a large amount of useful work into a small space of time. The syllabus can be obtained from Dr. Fletcher Little, 32, Harley-street, W.

FOOTBALL CASUALTIES.—On the 25th ult., at Maidstone, in a game between the Maidstone Invicts and Maidstone Reserves, an Invicta player, a youth aged sixteen years, "fractured his knee," and subsequently received medical treatment at the hospital, but blood poisoning supervened and he died on the 7th inst.—In a recent match at Warmley a player sustained a dislocation of his left jaw and also injury to one eye and the left side of his face.

ADDENBROOKE'S HOSPITAL: MUNIFICENT DONATION FROM MR. PECKOVER.—A quarterly court of the governors and subscribers of Addenbrooke's Hospital, Cambridge, was held at the hospital on Dec. 31st, under the presidency of the lord-lieutenant of the county (Mr. A. Peckover). The Finance Committee reported that the excess of expenditure over income amounted to £650. The deficiency was met in the happiest and handsomest manner by the chairman, who announced his intention of giving the hospital £1000.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—

A meeting of this society was held on Jan. 2nd, Dr. Tew, President, being in the chair. Dr. Bell Taylor showed ten patients, aged from forty-four to seventy-eight years, upon whom he had operated for Cataract, in most cases on both eyes. All had central and movable pupils and showed hardly any trace of the operation. Dr. Taylor also read a paper on the Accidents which are apt to occur during and after the Operation of Cataract Extraction. He described the earlier methods of operating, and pointed out the frequency of accidents resulting from them. The various methods adopted by Beer, Waldau, and von Graefe were mentioned. He preferred, he said, to use a modified Graefe's knife with a narrow blade of his own design, and for many years past had been accustomed to operate without iridectomy. A cataractous lens was sometimes larger than normal, and this condition greatly increased the difficulties of the operation. Escape of vitreous might take place when that medium was abnormally fluid or when the tension of the globe was increased. As a result there might be detachment of the retina or choroid or extreme collapse of the eyeball. In the case of excessive tension a preliminary iridectomy should be done. Prolapse of the iris into the wound should be treated by massage over the closed lids; if the pupil remained much displaced it might be necessary to do an iridectomy downwards. Inflammation and even suppuration of the globe might occur sometimes, but these accidents were not necessarily more frequent in the aged. On the appearance of inflammation leeching, cold, or astringents should be used.—Remarks were made by the President and Dr. Cattle and Mr. Laws.

ROYAL INSTITUTION.—On Tuesday next, Jan. 15th, Professor Charles Stewart, M.R.C.S., will deliver the first of a course of twelve lectures at the Royal Institution on the Internal Framework of Plants and Animals.

THE Italian journals, our Rome correspondent writes, express gratification at the election of Dr. Guido Baccelli as Honorary Fellow of the Harveian Society, recognising in the action of the society a tribute, not only to his therapeutic attainments, but to his high position and scholarly accomplishments.

THE annual report of the Devonshire Hospital and Buxton Bath Charity shows that 2656 in-patients were received during 1894. They included 2357 cases of a gouty or rheumatic character, 467 being complicated with some form of heart disease. The treatment demonstrated in the accustomed manner the remedial value of the Buxton mineral water. The financial position of the hospital is satisfactory, the receipts having exceeded the expenditure by £487.

THE POISON CASES AT WYLDE GREEN.—A series of cases of unexplained accidental poisoning on a large scale has occurred at the village of Wyld Green, near Sutton Coldfield, Warwickshire. On Saturday, Dec. 29th, an hotel proprietor, in accordance with usual custom at this time of the year, commenced the distribution of soup among the customers of the house and the poor of the district. In the course of the day many of those who had partaken of the soup were seized with sickness and diarrhoea, and by Jan. 2nd the number of sufferers amounted to at least 100. The meat used for preparing the soup is alleged to have been perfectly sound, and no irritant poison has been revealed by analysis. We are informed by the medical man in charge of many of the cases that a careful investigation is being made into the matter.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

CAMPBELL, DONALD, M.D., C.M. Glasg., has been appointed Medical Officer of Health for the Calne Rural and Urban Sanitary Authority.
COOK, WM. C., L.R.C.P. Edin., L.M., M.R.C.S., has been reappointed Medical Officer of Health, Bognor.
DUNLOP, J. G., M.B., C.M. Glasg., has been reappointed Medical Officer of Health, Long Sutton.
EDWARDS, G. M., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., has been appointed House Physician to the North-Eastern Hospital for Children.
FERNIE, EDWARD, M.D. St. And., M.R.C.S., has been reappointed Medical Officer of Health for the parish of Swymerton, of the Stone Union.
FLOYER, W. W., M.B. Lond., M.R.C.S., has been appointed Medical Officer for Thorpe, Surrey.
GRANT, ANDREW, M.D., Ch.M., Aberd., has been appointed Health Officer for the Oakleigh Borough, Victoria, Australia, vice W. H. Cutts.
HARDWICK, ARTHUR, M.D. Durh., D.P.H. Eng., has been reappointed Medical Officer of Health for the Newquay Urban Sanitary District.
INGLIS, DAVID, W., M.D., C.M. Glasg., has been appointed Medical Officer for the Hibernian Sanitary District of the South Shields Union, vice Mitchell.
IVENS, A. S., L.R.C.P. Edin., M.R.C.S., has been reappointed Medical Officer of Health for Walton-on-the-Naze.
JONES, A. L. D.S., R.C.S. Irel., has been reappointed Honorary Dental Surgeon to the Addenbrooke Hospital, Cambridge.
LATOCHE, A. D., L.R.C.P. Edin., L.R.C.S., L.M. Irel., has been appointed Medical Officer for the Southill Nether Sanitary District.
LAW, T. BROCK, M.B., C.M., has been appointed a District Medical Officer in the Colonial Medical Service, at Nicosia, Cyprus.
MACLENNAN, D. V., M.D., M.S. Edin., has been appointed Medical Officer of Health for the borough of Widnes.
PALMER, HOMAGE J., L.R.C.P. Edin., L.R.C.S. Edin., L.M., L.F.P. & S. Glasg., has been appointed Medical Officer of the Heath, Sutton-cum-Duckington, and Temple Normanton District.
PITT, CHAS. W., M.R.C.S., has been reappointed Medical Officer of Health for the Malmebury Rural and Urban Sanitary Districts.
RHODES, W. A., L.D.S., R.C.S. Irel., has been reappointed Honorary Dental Surgeon to the Addenbrooke Hospital, Cambridge.
ROBERICK, SYDNEY J., M.B., C.M. Edin., has been reappointed Medical Officer of Health for the Llanelly Urban Sanitary District and Port.
SHEARS, W., M.B. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed Junior House Surgeon to the Scarborough Hospital Dispensary.
UMNEY, WM. F., M.D. Lond., M.R.C.S., has been appointed Assistant Medical Officer to the Home and Infirmary for Sick Children, Sydenham, S.E.
WALDO, FRED. J., M.D. Camb., M.R.C.S., D.P.H. Eng., has been appointed Tutor in Public Health to St. Bartholomew's Hospital, Medical School.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

COUNTY ASYLUM, Prestwich, Manchester.—Pathologist. Salary £200 per annum, with furnished apartments, board, attendance, and washing.
DORSET COUNTY HOSPITAL, Dorchester.—House Surgeon, to reside and board in the hospital, unmarried. Salary £70.
GUEST HOSPITAL, Dudley.—Resident Medical Officer. Salary commencing at £100 per annum, increasing by £10 a year to £120 if services are satisfactory, with board, residence, and washing.
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physicians.
HOSPITAL FOR WOMEN (the London School of Gynaecology), Soho-square, W.—Clinical Assistants.
PARISH OF CAMBERWELL.—Clinical Assistant for the Infirmary of the Parish at Havill-street, Camberwell, for six months. Honorarium not exceeding £20, will be given on the termination of that period, if duties satisfactorily performed. Board, lodging, and washing, provided.
ROYAL HOSPITAL, Chelsea, S.W.—Dispenser. Remuneration 10s. a day, with unfurnished quarters, fuel, and light.
SHEFFIELD UNION.—Resident Assistant Medical Officer (single or widower) for the Workhouse and Children's Homes at Fir Vale, Pitsmoor. Salary £100 per annum, with apartments, rations, and the other usual allowances. Applications to the Clerk to the Guardians, Union Offices, Sheffield.
SOUTH-EASTERN FEVER HOSPITAL, Hatfield-street, New Cross, S.E.—Temporary Assistant Medical Officer. Salary £13 6s. 8d. per month, with board, lodging, attendance, and washing. Applications to the Medical Superintendent at the Hospital.
UNIVERSITY OF EDINBURGH.—Additional Examiners, for four years. Salary £75 per annum in each case, with an allowance of £10 per annum for travelling and other expenses in the case of an Additional Examiner not living in Edinburgh or the immediate neighbourhood. Applications to the Interim Secretary, University Court, University of Edinburgh.

Births, Marriages, and Deaths.

BIRTHS.

CRAIG.—On Jan. 5th, at Woodlee, Bridge of Allan, Stirlingshire, the wife of Staff-Surgeon William Maxwell Craig, R.N., H.M.S. *Rapid*, of a son.
ELLIOT.—On Jan. 5th, at Hawkwood, Chislehurst, the wife of Surgeon-Captain W. H. W. Elliot, 4th Punjab Infantry, of a daughter.
HICSON.—On Jan. 4th, at Old Bank House, Millom, Cumberland, the wife of J. Wasdale Hudson, L.R.C.P., L.R.C.S., L.S.A., &c., of a son.
LYNN-THOMAS.—On Jan. 5th, at Greenlawn, Pen-y-Lan, Cardiff, the wife of Mr. J. Lynn-Thomas, F.R.C.S., of a daughter.
MOIR.—On Dec. 12th, 1894, at South-street, Halifax, Nova Scotia, the wife of Surgeon-Captain John Drew Moir, Army Medical Staff, of a son.
MORRICE.—On Jan. 4th, at St. Ann's Lodge, Salisbury, the wife of George Gavin Morrice, M.D., M.R.C.P., prematurely, of a daughter.
NUTTALL.—On Jan. 4th, at 41, Great Bolton-street, Blackburn, the wife of Frank Nuttall, L.R.C.P. & S. Edin., &c., of a son.

MARRIAGES.

FERRARY-ANSFELL.—On Jan. 3rd, at St. Paul's Church, Grove-park, Chislewick, George Arthur Ferrary, L.R.C.P. Lond., M.R.C.S., of Birmingham, to Gertrude Somers, eldest daughter of William Henry Ansfell, surgeon, of Market Rasen, Lincolnshire.
QUILLER-KING.—On Jan. 1st, at the Chapel Royal, Savoy, Charles Turner Quiller, M.R.C.S., of Clapham, to Caroline, widow of James Walton King.

DEATHS.

BLANDY.—On Jan. 6th, at Netherwood-road, Shepherd's-bush, Alfred Addison Blandy, M.D. (late of Brook-street, Grosvenor-square), aged 69.
OPPENHEIM.—On Jan. 7th, at his residence, Orsett-terrace, Hyde-park, Lewis Oppenheim, M.R.C.P. Edin., M.R.C.S. Eng., aged 62.
PAGET.—On Jan. 7th, at Park-square west, Regent's-park, Lydia, the wife of Sir James Paget, Bart., in her 80th year.
PHILIPS.—On Jan. 6th, Philip George Philips of Russell-road, Kensington, M.R.C.S., aged 51, formerly of Queen's-road, Peckham.
SCHMIDT.—On Jan. 5th, at 150, Bethnal-green-road, Alfred Edwin Schmidt, L.R.C.P.E., L.R.C.S.E., L.S.A., aged 56.
SIMPSON.—On Jan. 6th, at the Royal Hospital, Chelsea, deeply regretted by all, Philip John Simpson, M.R.C.S. and L.S.A., in the fifty-sixth year of his age, son of the late George Simpson, F.R.C.S.
WRIGHT.—On Jan. 3rd, 1895, at King-street, Knutsford, William Charles Wright, M.R.C.S. Eng., L.R.C.P. Lond., aged 31 years, of enteric fever.

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), Gt. Northern Central (2.30 P.M.), King's College (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (9.15 A.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY.—INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (20, Hanover-square, W.).—7.30 P.M. Ordinary Meeting. 8 P.M. Dr. Porter (Stockport): Preventable Infantile Mortality, especially in connexion with Factory Labour. Discussion.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-sq., W.C.).—8 P.M. Paper:—Mr. C. S. Tomes: Some Points upon Amalgams. Casual Communications:—Mr. J. J. Andrews: On a very large Odontome (illustrated with lantern slides).—Mr. J. Mansbridge: A Method of draining the Antrum after Perforation.

SOCIETY OF ARTS.—8 P.M. Prof. Silvanus P. Thompson: The Arc Light. (Cantor Lecture.)

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Sir B. W. Richardson: Cycling and Heart Disease.—Dr. Hector Mackenzie: A case of Hysterical Deafness successfully treated, with some remarks on the Diagnosis and Treatment of this Affection.

TUESDAY.—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. H. D. Rolleston: Diffuse Secondary Growth on Dura Mater.—Dr. W. Collier: Enlarged Spleen.—Mr. Cecil F. Beadles: Five Brains from Insane.—Dr. T. W. Carr: Serous Pachymeningitis from a Syphilitic Child.—Mr. H. Snow: Identity of Duct Cancer of Mamma with ordinary Carcinoma.—Mr. C. P. White: On the Cultivation of the Diphtheria Bacillus in Hydrocele Fluid. Card Specimens.—Dr. F. Parkes Weber: Boar's Tusk forming a Circle.—Mr. Cecil F. Beadles: Ruptured Heart.

WEDNESDAY.—ROYAL METEOROLOGICAL SOCIETY (25, Gt. George-st., Westminster).—7.30 P.M. Ordinary Meeting. Mr. Charles Harding: The Gale of Dec. 21st–22nd, 1894, over the British Isles. 8.15 P.M. Annual General Meeting. Report of Council; Election of Officers and Council; Address by the President (Mr. R. Inwards).

ROYAL MICROSCOPICAL SOCIETY (20, Hanover-sq., W.).—8 P.M. Annual Meeting. Address by the President (Mr. A. D. Michael).

SOCIETY OF ARTS.—8 P.M. Prof. Vivian B. Lewes: Commercial Synthesis of Illuminating Hydrocarbons.

THURSDAY.—SOCIETY OF ARTS.—4.30 P.M. Capt. John Shakespear: The Lushais, and the Land they Live in.

HARVEIAN SOCIETY.—8 P.M. Annual General Meeting. President's Address: Smoking and Music.

SOCIETY OF ANÆSTHETISTS (20, Hanover-square, W.).—8.30 P.M. Dr. Frederic Hewitt: Nitrous Oxide and Oxygen.

THE MATRONS' COUNCIL (Medical Society's Rooms, 11, Chandos-st., Cavendish-sq.).—8.30 P.M. Conference. Miss Mollett: Infirmary Matrons under the Poor-law. Discussion.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

TUESDAY.—ROYAL INSTITUTION.—3 P.M. Prof. Charles Stewart: The Internal Framework of Plants and Animals (I.).

CENTRAL LONDON THROAT AND EAR HOSPITAL.—4.30 P.M. Mr. Lennox Browne: Diphtheria—the Elements of Prognosis and General Therapeutics.

WEDNESDAY.—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Gowers. ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq., W.C.).—5 P.M. Dr. Morgan Dockrell: Eczema.

THURSDAY.—ROYAL INSTITUTION.—3 P.M. Mr. W. S. Lilly: Four English Humourists of the Nineteenth Century (I.).

FRIDAY.—ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—11 A.M. Dr. Barratt: Introductory.

ROYAL INSTITUTION (Albemarle-street).—9 P.M. Prof. Dewar: Phosphorescence and Photographic Action at the Temperature of Boiling Liquid Air.

SATURDAY.—ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—11 to 1 P.M. Dr. Barratt: The Anatomy of the Skin. 5 P.M. Dr. Morgan Dockrell: Syphilis.

ROYAL INSTITUTION.—3 P.M. Mr. Lewis F. Day: Stained Glass Windows and Painted Glass (I.).

METEOROLOGICAL READINGS.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

COVER TO THE LANCET.

THE Manager begs to announce that at the request of many advertisers, and to keep pace with the ever-increasing demand for "position" pages, it has been decided to issue a cover to THE LANCET, commencing with the present number. The cover is printed on the same kind of paper as the journal itself, and thus ensures uniformity of appearance with past issues. With this exception of the cover the journal remains exactly as it was before. The Proprietors cannot consent to the insertion of advertisements in the centre of the paper—a position which has frequently been applied for, but which is annoying to the general reader.

THE INDEX TO THE LANCET.

THE Index for the last half-year was published in our issue of Dec. 29th, which completed the second volume of the year 1894. Those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Manager.

QUERIES ON URINE-TESTING AND OTHER TOPICS.

To the Editors of THE LANCET.

SIRS,—I shall be greatly obliged if you will give me answers to the following questions. 1. What is a reliable and convenient method of applying the phenyl-hydrazine test for glucose in urine? 2. What complete book do you recommend on urine testing and urinary deposits? 3. What book would you recommend on diseases of advanced age, with their treatment? 4. What artificial light is the best for ophthalmoscopic and laryngoscopic purposes? Is the incandescent gas light quite suitable? I am, Sirs, yours faithfully,

G. P.
Dec. 30th, 1894.
* 1. The mode of applying the phenyl-hydrazine test is thus described by Schwartz (Pharm. Zeit., xxxiii., p. 435): "The urine is first precipitated completely with lead acetate and filtered; the filtrate is mixed with a solution of phenyl-hydrazine and excess of potassium hydroxide (liquor potasse), and then boiled for a minute. If sugar is

present a yellow colour appears, followed by a yellow precipitate on adding excess of acetic acid. The formation of this precipitate is more significant than the development of colour, for the reason that boiling with potassium hydroxide slightly darkens the colour of normal urine. The object of precipitating with lead acetate is to remove uric acid, which, when acetic acid is added, may form a precipitate which might be mistaken for that indicating sugar."—2. A Guide to the Examination of the Urine, by Dr. J. Wickham Legg (seventh edition, H. K. Lewis); or Clinical Diagnosis, by Dr. von Jaksch, translated by Cagney (Griffin). We review this week favourably a similar work by Dr. Purdy published in Philadelphia.—3. The influence of age as a factor in disease is discussed in most medical text-books. We know of no recent book treating disease from this point only, but may mention the work of Dr. MacLachlan—"Practical Treatise on the Diseases and Deformities of Advanced Life" (London, 1863).—4. The electric light has been found successful. The incandescent gaslight possesses the necessary properties, but we are not aware that it is used yet for laryngoscopic purposes.—ED. L.

J. C. (Hulme).—1. Most "chemicals"—like the heathen in their blindness—bow down to wood and stone, and, for that matter, to vulcanite, in the sense that wood, stone, and vulcanite are very resistant to chemical attack attended with practical results. 2. We fear we must await further long and patient research before we can report the discovery of "a chemical which prevents sulphur from doing its duty." Moreover, to what duty does our correspondent refer? Does he desire to frustrate the effects of sulphur when administered in the form of brimstone paste, in accordance with Mr. Squeers' classic system? Or does he desire to remove its natural properties, in which case it seems to us that it would cease to be sulphur?

Mr. C. D. Cassidy.—The minutes of the Dental Committee and of the Executive Committee on Dental Business are published with the minutes of the General Medical Council and of the Branch Councils, and can be obtained by application to the publishers, Messrs. Spottiswoode. The numbers for 1894 are not yet published.

Struggles.—We have made inquiries for our correspondent, whose letter is not as explicit as it might be. The regulations are different in Scotland and Ireland to those prevailing in England (including Wales) and the Colonies.

"MUCUS IN THE EVACUATIONS."

To the Editors of THE LANCET.

SIRS,—In reference to the letter of "A Reader" under the above heading in THE LANCET of Dec. 15th, 1894 (p. 1461), I beg to offer the opinion that your correspondent's patient is suffering from chronic catarrhal dysentery—a disease which I myself have unfortunately suffered from for some months. The proper method of treatment is by daily evacuation and disinfection, for which purposes one or more teaspoonfuls of castor oil should be taken each night, and a capsule containing ℥ x of oil of turpentine every morning. If after a week or two oil of ricini is found too irritating, try small evacuant doses of sodium sulphate. The diet should consist principally of milk, with puddings, fish, eggs, fowl, rabbit, &c.; vegetables and butcher's meat should be avoided. I am indebted for the above most valuable suggestions to Dr. Ralfe, whose patient I have been for some time, and I am sure that if "A Reader" will persevere with the above method of treatment the same happy result will be attained in his case as in mine.

I am, Sirs, yours faithfully,

Ripley, Derby, Jan. 5th, 1895. F. C. WOOD, L.M. & S., L.S.A.

H. K.—Admission into the Army Medical Service is gained as the result of competitive examination. Under special conditions the admission may take place by nomination of the Secretary of State for War, such qualified candidates being proposed by the governing bodies of public schools of medicine in the United Kingdom or the Colonies. Candidates must, before being admitted to examination, possess the double qualification to practise medicine and surgery, and be registered under the Medical Act. They are also required to produce certificates of having acted as a medical clinical clerk for six months, as surgical dresser for another six months, and of having had not less than three months' instruction at an ophthalmic hospital or the ophthalmic department of a general hospital, including a course on errors of refraction. They must also furnish satisfactory certificates of moral character. Candidates must be between the ages of twenty-one and twenty-eight, in good mental and bodily health, and it should be stated whether they are of pure European descent. The candidate has also to be examined as to physical fitness by a Board of medical officers. These conditions being satisfied, he is admitted to the competitive examination, which is usually held in London twice a year, in the months of February and August. An entrance fee of £1 is payable at the conclusion of the candidate's physical examination if pronounced to be fit. No candidate is allowed to compete on more than two occasions. The subjects of examination are divided into compulsory and voluntary. The former comprise anatomy and physiology, surgery, medicine, including

therapeutics and the diseases of women and children, chemistry and pharmacy, and a practical knowledge of drugs. The eligibility of the candidate for admission into the service is determined by the result of this part of the examination. The voluntary subjects are French, German, comparative anatomy, zoology, natural philosophy, physical geography, and botany, with especial reference to *materia medica*. After having passed this examination the successful candidate is sent to the Army Medical School at Netley as "surgeon on probation," receiving a daily pay of 8s. and certain allowances, to go through a four months' course of instruction in the special duties required of him in the service.

Nemo Nihil.—We cannot insert the letter of our correspondent. It is a long indictment of his brethren, without a word of qualification or commendation. No class of the profession escapes—consultants, general practitioners, principals, all seem alike bad. Parsimony in our prosperous members; unprincipled and infamous use of professional position in ordinary practice; the meanest treatment of useful assistants—are the kind of qualities which he finds in medical practitioners. It is as if he had applied a microscope for the detection of every flaw and was absolutely blind to every virtue. We can be no parties to such one-sided judgment. That there are such persons may be admitted, as there are in every profession and calling. That they represent the profession we deny, and that such a wholesale accusation of the brethren in the name of Christianity is a good sermon for the opening year we altogether doubt.

Mr. G. H. Gabb.—We fail to see any serious or important difference between the two results of analysis. As to the analysis we published being a "chemical and physical impossibility," that is absurd, unless the same remark applies also to hundreds of analyses of milk published in well-known works. The amount of non-fatty solids was 9.25 per cent., but we have not stated how much of this was proteid and how much sugar.

"ON THE TREATMENT OF GLEET BY THE URETHROSCOPE."

To the Editors of THE LANCET.

SIRS,—I noticed in this club, the members of which are chiefly young men, a paper called *The Medical Week* in the library to-night. The paper is not taken in here, nor have I ever seen it here before. An article with the above title was marked on the cover in blue pencil.

I am, Sirs, yours faithfully,

Isthmian Club, Piccadilly, Jan. 6th, 1895.

M.D.

Thirteenth Wrangler.—There are illogical duchesses outside "Alice in Wonderland." We read in the *Lady* that their Graces of Hamilton and Sutherland, having met with accidents in the hunting field, have placed themselves under a bone-setter. There must be something unreasonably fascinating to the lay mind in being treated by the irregular practitioner, for no one who think—no one, in fact, who is logical—can seriously hold that the uneducated man is likely to know more than the educated.

Congratulations.—We are much obliged to our correspondent for his communication, but it is contrary to our practice to reply to articles that have appeared in the pages of a contemporary. Reference has been made to the subject of the appointment in the present number of THE LANCET.

Dr. Gairdner (Grieff, N.B.).—The specimen which our correspondent enclosed in his letter was submitted to our analyst, who reports that he found plenty of iron in it, but no distinct evidence of the presence of other metals could be obtained.

F. P. M.—Our correspondent might refer to the Army Medical Regulations on the subject of the physical examination of recruits, and to Dr. J. E. Pollock's "Medical Handbook of Life Assurance."

During the week marked copies of the following newspapers have been received:

—Levant Herald, Staffordshire Post, Glasgow Evening News, Lincolnshire Echo, City Press, Abingdon Herald, Newcastle Chronicle, Liverpool Courier, Birmingham Gazette, Morning Leader, Isle of Wight Observer, Brighton Argus, Warwickshire Times, Scotsman, Eastern Daily Press, Walsall Observer, Manchester Guardian, Sussex Daily News, Leicester Post, Northern Whig, Liverpool Daily Post, Science Shiftings, Leeds Mercury, Reynolds, Cork Examiner, Bristol Mercury, Mark Lane Express, Lloyds, Yorkshire Post, Courrier de la Presse (Paris), Times of India, Morecambe Times, Pioneer Mail, Coventry Mercury, Senate, Builder, Sanitary Record, Cork Constitution, Architect, Weekly Free Press and Aberdeen Herald, Local Government Chronicle, Cape Times, Public Health, Reading Mercury, Hertfordshire Mercury, Oxford Times, Surrey Advertiser, Local Government Journal, Australian Medical Journal, Boston Independent, West Middlesex Standard, Aglaria, Royal Cornwall Gazette, Bambury Guardian, Pembroke Gazette, Burton Chronicle, Nottingham Daily Express, Public Opinion, Gravesend Standard, Madras Times, Oban Times, East Sussex News, Blackpool Gazette, Torquay Times, Cambridge Express, Essex Telegraph, Devon and Exeter Daily Gazette, Walton Gazette, &c., &c.

The Manager cannot hold himself responsible for the return of testimonials &c. sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom; advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8 Rue Traversière, Amiens, Paris.

A Presidential Address

ON

THE SANITARY NEEDS AND ASPIRATIONS OF INDIA.

Delivered before the Indian Medical Congress in St. Xavier's College, Calcutta, on Dec. 24th, 1894.

By SURGEON-COLONEL R. HARVEY,
M.D. ABERD., F.R.C.P., D.S.O., V.H.S., I.M.S.,
PRESIDENT OF THE CONGRESS.

[SURGEON-COLONEL HARVEY commenced with a few graceful words of thanks to the Viceroy of India, the Earl of Elgin, for presiding and of acknowledgment of the unwearied exertions of the secretaries.]

I will now try to indicate in the briefest way what modern medicine has done, is doing, and may hope in the future to do for India. The subject is so vast that it can be given in outline and no more—a mere scene-painter's sketch, not a finished picture. By modern medicine I of course mean the science introduced from Europe by the earliest medical officers of the Honourable East India Company. From the small beginnings made by them has developed by natural evolution our system of hospitals and dispensaries, sanitation, vaccination, and medical education as they exist to-day, and from which we hope that a further development may take us in time to things unattempted yet. It is a curious fact that it was in gratitude to a medical envoy for professional services that the first firman was granted to the Company by the Emperor of Jehangir. In the earlier days of the Company, and, in fact, up to the evil times of 1857, and to some extent even yet, we find medical officers in the most incongruous and unexpected positions and places—residents and envoys at foreign courts, commissioners and deputy commissioners, superintendents of gunpowder factories, postmasters-general, heads of such departments as the telegraph, masters of mints, and so on. This, I take, was due in great measure to the fact that in the earlier days both civilians and military officers came out so young that they were beaten in the advantages education gives by the older and more scientifically trained medical officers. The medical science of that day we should now look upon as very primitive, but it was the best that was to be had and did yeoman's service to the Company and the people. As the red boundary line of England's influence extended, dispensaries and hospitals sprang up in all the large cities and brought relief to many—specially surgical relief. The idea of preventive medicine had not yet been born even in England, so that no sanitary service was attempted. Vaccination was, however, started within two years of its discovery by Jenner, and a beginning was made with medical education. From a very early time native doctors, as they were then called, were trained at the local dispensaries, beginning as apprentices or even as hospital coolies, picking up what they could at the bedside, aided by informal teaching from the civil surgeon. The results, strange as it may seem, were sometimes surprisingly good. I have seen lithotomy and cataract operations ideally perfect in technique, finish, and result performed by a man who had never attended a medical school and knew next to nothing of anatomy. As a rule, however, the results were not satisfactory, and an enormous advance was made when, in 1832, a vernacular medical school was started in Calcutta. Systematic medical education really began, however, with the opening of the Medical College of Bengal in 1834, followed by that at Madras in 1835 and at Bombay. In all those the instruction was in English. The Vernacular Medical School in Calcutta was followed by one at Hyderabad, founded in 1846; another at Agra, in 1855; and one at Lahore, in 1860. When I came to India, in 1865, these were the only schools.

I tried to get for this address a statistical statement showing the chief medical and surgical results obtained throughout India in 1865. The first year for which complete statistics are available is, however, 1877. If the progress between 1865 and 1877 was at the same rates as between 1877 and 1893, we should have to halve the figures of 1877 to arrive at those of 1865. In 1877, then, 6,142,070 patients were

treated in 1147 hospitals and dispensaries, 4,633,105 vaccinations were performed, 2682 operations for stone, and 2372 for cataract. These were great results, and reflect the utmost credit on the officers who attained them; but they were nothing in relation to the population and true needs of the country. Small tentative efforts had been made to introduce sanitary improvements—I am now speaking of 1865,—but systematic sanitation, as we know it, had not begun. The Sanitary Department, though its formation was under consideration, had not been constituted, and the death-rate of the European troops had from the beginning of the century reached the appalling annual average of 69 per mille. A Royal Commission sitting in 1864 ventured to express a hope that the introduction of scientific sanitation might reduce this to 20 per mille, and the creation of the Sanitary Department, as a result of their recommendations, may be taken as a boundary line dividing the past from the present of medical work in India. My period of service, now close on thirty years, coincides with this. It has been marked by enormous progress in all directions. Medical colleges, in which a complete education is given in English, have been opened at Lahore, Allahabad, Tanjor, and Nellore and affiliated to the universities. At Hyderabad the classes have been taught in English since 1882. Additional vernacular medical schools for the education of civil hospital assistants and civil medical practitioners are now working at Sealdah, Patna, Dacca, Katak, Poonah, and Ahmadabad.

The medical education of women has also been recently introduced, and girls are now trained for the purposes of the Dufferin Fund at most of the medical schools. The number of hospitals and dispensaries open last year was 2025, in which were treated 16,973,468 patients, increases of 76 and 178 per cent. over 1877. There were 4476 operations for stone and 20,279 for cataract. Vaccination has been enormously extended and put on a much more systematic footing, 7,502,024 operations were done, an increase of 62 per cent. These figures indicate great activity and afford ground for congratulation, yet, compared with the wants of the country, indicate that they still touch but the fringe of the population. In Bengal, for instance, only one-fifteenth of the people are within five miles of a dispensary, and a considerable percentage of the children born escape vaccination, so that bad epidemics of small-pox are still possible. Of recent years an entirely new development has taken place in the organisation of special hospitals for women, officered by medical women, under the fostering care of the noble Lady Dufferin, whose name, like Milton's, should resound for ages among the zenanas of India. Still in its infancy, it is doing enormous good to a class whose needs are of the sorest, and it is, I believe, destined to flourish and increase till every important town in India has its Dufferin Hospital side by side with its hospital for males. Sanitary progress, however, is the chief feature of the last thirty years, and more especially of the last decade. I have told you how the death-rate of British soldiers up to 1857 averaged 69 per mille, and that the Sanitary Commission ventured to hope it might be reduced to 20. This estimate was too modest, for since 1882 it has never exceeded 15, except in 1889, when it was 16.6, less than a quarter of the previous rate. The reduction has been effected by hygienic reforms of all kinds, but especially by the gradual improvement of the water-supply in cantonments—first, by cleaning and protecting wells and tanks and setting them aside for drinking purposes only—a plan which has been followed for many years; and of recent years by scientifically devised water works provided with all the latest improvements. A glance at the two maps on the wall will give a better idea than any words can of the great recent advances in this direction. The first, representing the India of 1865, is like the chart of the shark-hunters, "a perfect and absolute blank." The second shows the cities, towns, and cantonments now properly supplied, or in course of being supplied, with pure water. In those with dotted lines the works are in hand, but not yet in operation. The Cawnpore works are complete in the town, but have not yet been extended to the cantonment. The Marri water scheme supplies Dunga Gali, Kyra Gali, Bawan, Kuldanna, Clifden, Gbrial, and Thopia, as well as the Marri Bazaar, cantonment, and civil station. It cost 720,000 reils. The whole of the troops in the hills near Marri, numbering some 5000, are thus supplied with pure water. Many additional schemes are under consideration. It has long been the fashion to poke fun at the Sanitary Department, to denounce it as a sham and a pretence, [producing reports which lead to nothing—*not et*

præterea nihil,—and sanitary officers themselves have sometimes felt that much of their labour was of the Sisyphean sort in the absence of any means to enforce and carry out their recommendations. The map seems to me to point to encouragement instead of despair. Even in England modern sanitation is a thing of the present century—mainly of the last half-century; finality has not been reached, and popular ignorance and prejudice and vested interests still block many possible improvements. In India, where *stare super vias antiquas* (what was good enough for our fathers is good enough for us) is a sentiment deep-rooted in the hearts of the people and is almost a part of their religion, it is small wonder that the progress has been slow. Still, the progress is there, and in India, as elsewhere, tends to acquire continually increasing force and volume as it proceeds. Municipal Acts containing provision, *inter alia*, for sanitary measures, village sanitation Acts specially designed *ad hoc*, have been embodied in our laws, and, though mainly permissive, can be extended by notification to such places as seem sufficiently advanced to accept them. Sanitary boards on which is a sanitary engineer are now established in most provinces. Various schemes are on foot for extension of waterworks, drainage, and other improvements. Sam Slick has warned us not to prophesy unless we know. I will not prophesy, but will now try to indicate a little more fully in what directions progress is likely and desirable, the difficulties in the way, and the means of overcoming them. No one is more thoroughly aware than I how little the great deal that has been done is, compared with what is left to do, and no one can recognise more fully the difficulties in the way of affecting such a general reform as shall satisfy Europe. When asked what India wants from medical and sanitary science, I am tempted to use the words of the ragged urchin in *Punch*, who replied to a similar question, "I think I want most everything." Let me enumerate the needs: first medical, then sanitary. We will take the question as to the means of providing for them later. The first and greatest is like Cerberus—three-headed. To bring the advantages of modern medicine within reach of all, we require a great extension of hospitals and dispensaries, officered by a class of locally-trained practitioners of higher professional attainments than the average of those educated at existing schools. Another need felt greatly by the profession is that of some such Acts as the Medical Acts of England, by which properly educated and duly qualified men may be distinguished from the hosts of quacks, charlatans, and impostors who everywhere abound. Another great and crying need both for the profession and the public is the extension to India of those modern discoveries which are so fruitful for good in Europe, and which have such splendid potentialities of future development. It is not creditable that India, whose crowded millions are as interested as any in the solution of the problems of disease and the provision of remedies, should be doing nothing to bring about such desirable results. It is not to the credit of England that when the plague breaks out in a Crown colony she should be dependent on a country like Japan for a demonstration of the cause of it. This need will be met and India take her proper place among those countries which are trying to advance science for the benefit alike of men and animals when the Pasteur Institute of India is established. That institute we mean to have, and to have mainly as the result of private enterprise. Our success has been so far hampered by the well-meaning efforts of kind-hearted persons who have let their imaginations run away with them. This is not the place to discuss the question of vivisection. I am about to deal with it elsewhere, and hope to be able to convince all but a few irreconcilables that the institute is entirely justifiable, and that sensitive and humane men may freely subscribe to it, as I again ask them to do. I must be allowed, however, to protest publicly against baseless charges of abominable cruelty levied against the medical profession as a body. I claim, and I believe public opinion will support me, that no profession is more full of sympathy for suffering or more prompt and eager to relieve it. It is these same irreconcilables or others of a like kidney who, ignoring the alcoholic beam in the eye of England, wish to remove the opium mote from the eye of India regardless of the wishes and interests of her people. It is they, too, who prevent us from preventing preventable disease, and thus make themselves individually instrumental in causing the conveyance of a horrible malady to numbers of innocent women and children, and in allowing the admissions from these diseases to rise from 15,006 in 1883 to 32,663, or 466

per mille per annum, in 1893, figures which represent three regiments permanently in hospital and useless to the taxpayer. It is time that the common-sense of mankind should refuse to be dictated to by a minority of imperfectly informed and unscientific persons whose zeal is in inverse ratio to their knowledge. These then are the chief medical, I now pass on to the sanitary, needs of India.

[Surgeon-Colonel Harvey here pointed out the difficulties to be encountered in any attempt at State-regulated sanitation in countries like India, and continued.]

Praise is constantly lavished on England on account of what she does for sanitation, and the praise is thoroughly deserved. But England is relatively a small country and enormously rich. India is, on the other hand, one of the largest, most populous, and poorest of countries. The standard of comfort as measured in terms of European economics is low, though, as the wants are few, it is really higher than it seems. The population of Great Britain and Ireland is under 38 millions, that of India over 222 millions, excluding nearly 67 millions in native States. The revenue of England is in round numbers and excluding local items £91,000,000 in pounds sterling, that of India 64 millions in tens of rupees, and so terribly has that poor coin, like Lucifer, fallen from his high estate that, in spite of equalling or exceeding, as was the case thirty years ago, the pound sterling, ten rupees, is at present exchange only worth eleven shillings. The income of India is thus represented in sterling by £36,000,000. The revenue per head in England works out £2 8s., in India three shillings and threepence, or in the proportion of fourteen to one. Sanitary works also are probably more expensive in India than in England, for though labour is cheaper and engineering difficulties less, the trained staff is much more expensive, and much of the material has to be imported. The people are unwilling and the Government is unable to provide means for efficient sanitation *per saltum*. Are we, then, to conclude that the problem is insoluble, a conundrum to be given up, and that we should sit down with folded hands and do nothing? I have many times heard the note of despair; I know that many men consider our efforts to be hopeless and our views the dreams of visionaries, blind to facts and deaf to the voice of experience. I confess, gentlemen, that I take a more cheerful view than this; and while fully recognising the difficulties I have pointed out refuse to impale myself on either horn of the dilemma. I hold that it becomes no man to brook despair, that by sitting still in face of a recognised evil instead of contending against it we make ourselves responsible for it, and that it is only by "pegging away" that progress is possible. Our friends, the Fathers, will tell you that a "counsel of perfection" is the highest ideal of excellence, to be kept in view and striven for, although hardly to be attained by frail mortals. A model India with all the latest sanitary improvements is such an ideal. The man of little faith says: "It is high, you cannot attain unto it." We can at least seek after it, and toiling hard against the stream of prejudice and difficulty see distant slopes of a sanitary Eden gleaming in the distance. As George Herbert says—

"Who aimeth at the sky
Shoots higher far than he that means a tree."

An Address

ON

HEMIPLEGIA.

Delivered to the Medical Book Society of Leamington at the
Warneford and South Warwickshire General
Hospital on Dec. 1st, 1894,

By NORMAN MOORE, M.D. CANTAB.,
F.R.C.P. LOND.,

ASSISTANT PHYSICIAN AND LECTURER ON MEDICINE TO
ST. BARTHOLOMEW'S HOSPITAL.

GENTLEMEN,—I propose this evening to consider some of the steps by which our present knowledge of hemiplegia has been attained and to point out some directions in which additions to it may be made; and in discussing this single chapter of the vast subject of nervous disease I shall venture to begin by trying to determine the earliest connexion of this

branch of medicine with our island. The inquiry will carry us to the very beginning of our written history. Quintus Cicero, brother of the great orator, was an officer in the army of Julius Caesar in Britain in 54 B.C., and in a letter which he wrote from this country to his brother he asks about the poems of Lucretius, and his brother answers: "Lucretii poemata ut scribis ita sunt: non multis luminibus ingenii, multæ tamen artis."¹ They were both interested in their contemporary the poet, whose poems were probably edited soon after by the orator. In the famous poem, "De Rerum Natura," in which Lucretius sets forth the Epicurean philosophy, is a description² of a nervous disease of which we have all seen examples. In reading it we must remember that the poet dwells upon the symptoms as illustrations of his argument that the soul is inseparable from the body, is a mere part or function of it, and lives or dies with it. I shall quote the translation of Munro, the greatest modern student of Lucretius:—"Moreover, it often happens that someone constrained by the violence of disease suddenly drops down before our eyes as by a stroke of lightning, and foams at the mouth, moans and shivers through his frame, loses his reason, stiffens his muscles, is racked, gasps for breath fitfully, and wearies his limbs with tossing. Sure enough because the violence of the disease spreads itself through his frame and disorders him, he foams as he tries to eject his soul, just as in the salt sea the waters boil with mastering might of the winds. A moan, too, is forced out because the limbs are seized with pain, and moans because seeds of voice are driven forth and are carried in a close mass out by the mouth, the road which they are accustomed to take, and where they have a well-paved way. Loss of reason follows, because the powers of the mind and soul are disordered, and, as I have shown, are riven and forced asunder, torn to pieces by the same baneful malady. Then, after the cause of the disease has bent its course back and the acrid humours of the disordered body return to their hiding-places, then he first gets up like one reeling, and by little and little comes back into full possession of his senses and regains his soul." Munro thinks that this passage is based upon one in some medical text-book of the time, and both Hippocrates and Galen give abundant evidence that the epileptic convulsion had been carefully observed by them; but, whether verified from a treatise on medicine or drawn from life, this description of epilepsy in Lucretius has an especial interest for us, since we may justly regard it as the first account of a nervous disease read by a resident in England. It is impossible not to inquire at the same time whether Quintus Cicero's commanding officer was the first patient connected with Britain of whose nervous disease we have a record. It is often stated that Julius Caesar had epilepsy. The assertion is based on a passage in Suetonius which relates that on two public occasions he had epilepsy.³ No authority is given for this statement, and though Suetonius was a writer careful as to fact and who probably had good authority for most of his statements, it must be remembered that he wrote more than 150 years after the death of Caesar, and that the current accounts of the appearances of ill-health of public men on public occasions are very inaccurate even in their own time and tend to become much more so after the lapse of years. That Caesar's health was breaking before his assassination seems probable from another passage in Suetonius.⁴ It is certain that he was subject to tremendous anxiety, and he may easily have exhibited some of its results. The attacks of loss of consciousness, if they took place, may have been fainting fits due to cardiac or cerebral weakness. Had Antistius, the physician, whom Suetonius quotes as stating from his own observation that but one of the twenty-three wounds of Caesar was a fatal one, also asserted that his two seizures were true epilepsy there would have been no room for discussion. In the absence of such evidence I can only say that the wonderful head, bearing, and countenance of Caesar as shown in antique sculpture

show a mental power and force of character wholly unlike anything which I have ever seen in an epileptic patient.

To return to Lucretius. If his account of epilepsy is based on a medical treatise extant in his day, can we add much to the knowledge of that time? Let us examine that knowledge once more in another author: Aurelius Cornelius Celsus, who wrote nearly a hundred years later, but whose general learning entitles us to assume that he had read all the books on medicine belonging to the period of Lucretius. Celsus⁵ says: "Inter notissimos morbos est etiam is qui comitialis vel major nominatur. Homo subito concidit, ex ore spumæ moventur; deinde interposito tempore ad se redit et per seipsum concurrit. Ac solet quidem etiam longum esse usque ad mortis diem et vitæ non periculosum." His descriptions of disease, concise but not lifelike, and his infrequent mention of some slight common observations incline me to the view held by some authorities on other grounds that Celsus was not a working physician; but though there are few details in this account he tells enough to show that the fit was well known and carefully observed in his time. What can we add as a result of the observations of eighteen centuries on epilepsy? Chiefly the discovery of Dr. Hughlings Jackson about the local anatomical cause of some epileptic fits and the method of treatment with bromide of potassium. Yet in no branch of medicine has greater advance been made in this century than in the subject of nervous diseases, and the existing knowledge of hemiplegia is an encouraging example of this progress. Hippocrates had noticed that one side of the body was often paralysed, that this condition sometimes followed an apoplectic fit, that after an injury to one side of the head paralysis of the other side of the body sometimes took place, and that wasting of the paralysed muscles was a sequel to the loss of power.⁶ In the books of the Middle Ages the assertion that an injury on one side of the head may be followed by paralysis on the other side of the body is often repeated, whether as matter of compilation or from observation of the fact it is often difficult to know. John Mirfield the first medical writer connected with St. Bartholomew's Hospital, who wrote in the reign of Richard II., observes that an injury on the right side of the head is likely to lead to paralysis on the left side of the body, and he relates the case of one of the canons regular of St. Austin resident in the Priory of St. Bartholomew in Smithfield.⁷ The canon was about to mount his horse, and when he wished to seat himself in the saddle the horse rose on his two hind legs and the canon fell head downwards over the crupper of the horse to earth, and fell so heavily upon his head that straightway he lost the sensation and movement of his whole body. Mirfield's master, having been called by the friends of the patient, made them shave his head, and then rubbed in oil of roses with a quart of warm vinegar, and sprinkled it with a powder and put over it a fine cloth soaked in oil and vinegar, and over that fastened bandages, and over all the skin of a lamb. Ointment was also rubbed into the patient's neck. On the second day the patient opened his mouth a little. On the third day, when a question was put to him, he made a stammering attempt at an answer, but could not form the words. On the fourth day he spoke stammeringly, and then they handed him a thin warm drink, which he saw and swallowed. The fifth day he took a thin tisane, and on the sixth they gave him chicken broth. He then began to grow stronger and to be able to move, but it was many days before he could walk. He was recommended to eat the brains of birds and kids, and thus doing he was cured. But he was never after of such subtle wit and good memory as before.⁸

The first great addition to the knowledge current in the medical world in relation to hemiplegia was made seven months after the death of Harvey; but, before proceeding to consider it, it is impossible to go on without asking whether the great discoverer of the circulation had thought over the structure and functions of the nervous system and their disorders. In the original manuscript notes of his lecture "De Musculis," which has on two pages the date 1627, the year before the publication of his "De Motu Cordis et Sanguinis," and which is scarcely less worthy of publication than those notes of his lectures of 1616 which were edited in 1886 by a committee of the Royal

¹ Epist. ad Fratrem, Book II., cap. II.

³ valetudine prospera; nisi quod tempore extremo repente animo linqui, atque etiam per somnum exterreri solebat. Comitialis quoque morbo bis inter res agendas correptus est. Suetonius: Julius, cap. xlv.

⁴ Suspicionem Cesar quibusdam suorum reliquit, neque voluisse se diutius vivere, neque curasse, quod valetudine minus prospera uteretur. Julius, cap. lxxvii.

⁵ Book III., cap. xxiii.

⁶ Epidemics, Book vii., 35.

⁷ Manuscript of Breviarium Bartholomei, written in 14th century, now in library of Pembroke College, Oxford, fol. 191a.

⁸ Ibid., fol. 192. De Morione Cerebri ex Casu vel Percussione.

College of Physicians of London, there are some indications of his views on the nervous system. The manuscript of 1627 is written in the curious mixture of Latin and English which Harvey used in all his memoranda. The following notes show that he discussed the functional relation of the several parts of the nervous system.

An Cerebrum, rex;
Nervi, magistratus;
Ramuli nervorum, officiales;
Musculi, cives, populus?

An Cerebrum, master; Spina, his mate;
Nervi, huteswayne;
Musculi, sailors?

On the opposite page he inclines to another view of the chief command in the human body.

An WH⁹ potius—
Cor, Imperator-rex;
Cerebrum, judex, sergeant-major, prepositus;
Nervi, duces, magistratus;
Ramuli, decuriones, constabiles;
Musculi, milites?

An Cor, captain, factor, owner;
Cerebrum, master of the ship;
Nervi, masters' mates, boys, officers;
Musculi, nautae?

And in a long note, of which I have had a photograph taken, he lucidly distinguishes several morbid conditions of the nervous system. As the reproduction gives the full text, I have not tried to do more than make the headings clear.

Harvey died on June 3rd, 1657, and on Feb. 2nd, 1668, Dr. John James Wepfer finished his "Observationes Anatomicæ ex Cadaveribus eorum quos sustulit Apoplexia, cum Exercitatione de ejus loco affecto," published at Schaffhausen in that year. He was an enthusiastic morbid anatomist, and says in his preface: "To soil the hands with blood and gore seems to some a mean and low occupation, but a little water can wash away this disgrace. Ignorance of things anatomical is far more shameful which ensures discredit to ignorant physicians and surgeons which neither the Rhine nor the Ocean can wash away." He describes four cases of apoplexy, and proves that it may be due to cerebral hæmorrhage, which is not caused by external injury, but by internal morbid change, a notion familiar to us but quite new in his time. He afterwards added more histories, and the candour with which he states cases which he cannot explain and which may tell against his argument shows his scientific merit. His prolixity of style has, perhaps, made him less read than he deserves. English medical writers of his time allude to him so little that I was pleased to find a copy of his book in an old library in the Highlands of Scotland, bought when new by the chief of the clan as worthy a place in the family collection of books. In a later edition of this excellent book (Amsterdam, 1724) cases observed by other physicians are appended, and among them one which must be interesting to everyone who has studied medicine—that of the physician whose memory is daily celebrated in schools of medicine in relation to the skin, the spleen, and the kidney, Malpighi. In the colleges at Cambridge it is customary in each to set apart one day in the year to the commemoration of benefactors.

* WH is his usual indication that he regards a statement as especially significant.

The members of the college meet in the chapel, the roll of benefactors is read and a sermon delivered on their merits, and a feast in the college hall concludes the observances of the day. The commemoration of benefactors to our study, if less ceremonial, is more frequent. In what school of medicine is the name of Glisson not mentioned daily? His capsule is a mantle of fame. Lower is prominent by his tubercle; the circle of Willis keeps him in touch with his profession, though he has been dead more than two centuries; the antrum which Highmore explored is a refuge for him from forgetfulness; nor is Tulp more set forth to future ages by the brush of Rembrandt than by his daily mentioned valve; Wharton along his duct, the second Monro through his foramen, pass to scientific immortality. Malpighi was aged sixty-six, and had had gout as well as the cardiac signs of chronic interstitial nephritis and of renal calculus when, on July 25th, 1694, he was attacked by apoplexy followed in four days by right hemiplegia. He lingered till Nov. 29th, and then died with a fresh access. Post mortem the left ventricle was found two fingers thick, the right kidney with dilated pelvis, a small calculus in the bladder, two pounds of black blood in the right cerebral ventricle, and yellow fluid in the left. The bloodvessels of the brain were dilated. The post-mortem examination was made by the well-known Dr. George Baglivi.

In 1684—six years after Wepfer's book—the "*Cerebri Anatome*" of Dr. Thomas Willis was published in St. Paul's Churchyard, a frequent place of publication for books at that time, but one especially appropriate to this anatomy, in which several of the drawings were from the hand of Christopher Wren. Eager for all kinds of knowledge, Wren had made both dissections and drawings for Willis. This book thoroughly investigates, as a result of original dissection, the anatomy of the nervous system, but adds nothing to its morbid anatomy. Thenceforward the anatomy of the brain was well known to all students of medicine through Willis's book. Dr. Richard Lower is thanked by Willis in his preface, who acknowledges "*et cultelli et ingenii aciem*" (the sharpness both of his scalpel and his mind). Wepfer had demonstrated the anatomy of apoplexy in 1658; Lower in 1664 knew thoroughly the normal anatomy of the brain. Yet so little had the importance of Wepfer's discovery been recognised in England that when Charles II. in 1685 died with the symptoms of apoplexy, cerebral hæmorrhage was not mentioned as its cause; nor when at the necropsy the brain was found "in great disorder," so that "no judgment could be made concerning it,"¹⁰ and with actual hæmorrhage visible, did Lower or any of the other physicians present point out that the hæmorrhage had caused the disorder of the brain, and that both were the cause of the apoplectic symptoms. The king was aged fifty-three. Bishop Burnet,¹¹ who had conversed with many of the eye-witnesses of the facts, states that he had been out of sorts on Feb. 1st, 1685, and had eaten little. He had a restless night. Sir Edmund King, one of his physicians, came in the morning and, Burnet's account shows, found him in a condition of partial aphasia. "The doctor concluded," says Burnet, "he was under some great disorder either in his mind or in his body. The doctor, amazed at this, went out, and meeting with Lord Peterborough, he said the king was in a strange humour, for he did not speak one word of sense." When he went back with Lord Peterborough "the king, who seemed all the while to be in great confusion, fell down all of a sudden in a fit like an apoplexy." Sir Edmund King knew a good deal about the brain, for he had dissected a hundred human brains.¹² He bled the king, who became conscious, but when put to bed seemed oppressed and on the verge of another fit. On Feb. 5th he had another fit. The physicians said he would not live, and he died on the next day at 11 A.M. The exhortations of Sancroft and of Ken, the questions of James, the offices of Huddleston, and the numerous set remarks the king is reported to have made were occurrences of the period between the second seizure and his death. In the extended reading on which Lord Macaulay's account of Charles II.'s death is based there is one obvious omission. The great historian seems never to have considered the medical aspects of the case or the probability of a man dying from cerebral hæmorrhage, of which the first indication was partial aphasia, making neat or thoughtful replies during the last twenty-four hours of his life. Much of the evidence as to the king's state of mind and sayings is open to the objection that, though it was that

of eye-witnesses, it was written down long after the event. No witness had better opportunities of observation than James II., who was at the King's bedside when he died and for many hours of his illness. His "*Récit de la Mort du feu Roi d'Angleterre Charles II.*"¹³ was made to the nuns of Chaillot on Sept. 10th, 1692. He had no doubt as to the apoplexy. He is anxious to make clear his brother's rejection of the ministrations of the Anglican divines and his explicit acceptance of those of Father Huddleston. Reading the account in the light of our ordinary experience of such cases it seems probable that Charles could express assent and dissent, that a murmur and a nod were the actual indications which are represented in the account of James by the words "I would give all I have in the world to have a priest"; and that the drawing aside of the bed-curtains, of which James says "*pour voir, dit-il, lever le soleil pour la dernière fois*," was not asked for in this form but suggested by some murmur and restless gesticulation of the left arm. The "*Récit*" itself contains evidence that James had varied in the details of his account. The reason most likely was that it was an interpretation of Charles II.'s movements and expressions and not a precise report of words, which were probably few, disjointed, and inappropriate to the meaning obviously intended. The chief interest of the King's case is that its history throughout shows how little knowledge was prevalent on the subject at the time in spite of the discoveries of Wepfer and the careful dissections of Willis and Lower.

It is interesting to note Burnet's account of another case of aphasia in the same period, that of Archbishop Tillotson, "who was taken ill," says Burnet, "of a fit of a dead palsy" in November while he was in the chapel at Whitehall on a Sunday. He died the fifth day after he was taken ill. His distemper did so oppress him and speaking was so uneasy to him that though it appeared, by signs and other indications, that his understanding remained long clear, yet he was not able to express himself so as to edify others."¹⁴

The case of Dr. Samuel Johnson in June, 1783, is an interesting example of aphasia without any hemiplegia and with slight agraphia. He describes the attack in a letter to Mrs. Thrale written two days after it, and less fully in two letters, one to Mr. Edmund Allen, the other to the Rev. John Taylor, both written on the day of the attack.

"I went to bed," he says in the letter to Mrs. Thrale, "and in a short time waked and sat up, as has been long my custom, when I felt a confusion and indistinctness in my head, which lasted, I suppose, about half a minute. I was alarmed and prayed God that however he might afflict my body he would spare my understanding. This prayer, that I might try the integrity of my faculties, I made in Latin verse. The lines were not very good, but I knew them not to be very good. I made them easily and concluded myself to be unimpaired in my faculties. Soon after I perceived that I had suffered a paralytick stroke and that my speech was taken from me. I had no pain and so little dejection in this dreadful state that I wondered at my own apathy, and considered that perhaps death itself when it should come would excite less horror than now seems to attend it. In order to arouse the vocal organs I took two drams. Wine has been celebrated for the production of eloquence. I put myself into violent motion and, I think, repeated it; but all was vain. I then went to bed and, strange as it may seem, I think, slept. When I saw light it was time to contrive what I should do. Though God stopped my speech he left me my hand; I enjoyed a mercy which was not granted to my dear friend Lawrence, who now, perhaps, overlooks me as I am writing and rejoices that I have what he wanted. My first note was necessarily to my servant, who came in talking, and could not immediately comprehend why he should read what I put into his hands. I then wrote a card to Mr. Allen that I might have a discreet friend at hand to act as occasion should require. In penning this note I had some difficulty; my hand, I knew not how nor why, made wrong letters. I then wrote to Dr. Taylor to come to me and bring Dr. Heberden, and I sent to Dr. Brocklesby, who is my neighbour. My physicians are very friendly and give me great hopes; but you may imagine my situation. I have so far recovered my vocal powers as to repeat the Lord's Prayer with no very imperfect articulation. My memory, I hope, yet remains as it was; but such an attack produces solicitude for the safety of every faculty."¹⁵ In a letter written a fortnight later to

Boswell he mentions that he "could say *no*, but could scarcely say *yes*"—a peculiarity which, as far as my experience goes, is commoner than the converse condition in cases of aphasia. When Dr. John Cooke, physician to the London Hospital, in 1820 published his "Treatise on Nervous Diseases," no further advance had been made, although, of course, the great discovery of Sir Charles Bell already worked out, though not yet fully set before the world, was the first step towards a future rapid advance. How rapid and how great that advance has been a comparison of the two volumes of the treatise of Dr. Cooke and the two volumes of Dr. Gowers' "Manual of Diseases of the Nervous System" will clearly show. In the earlier book the minute structure of the nerves, cord, and brain are all unknown, and nothing clear is stated of their functions. The advances on the anatomy of Willis of 1664 are few and insignificant, and his views of the functions of the brain, if not accepted, are certainly not replaced by any other opinion. No trace of the careful distinction of diseases and of their localisation in the brain is to be found. Aretæus¹⁶ had noticed in the second century that the pupils in paralysis were sometimes contracted and sometimes dilated, and Dr. Cooke can say nothing further on the point. In the seventy years between Dr. Cooke and Dr. Gowers the whole minute anatomy of the nervous system has been described, its gross anatomy revised throughout, and the subject of cerebral topography created, besides numerous other conversions of absence of knowledge or of doubt into certainty by the general advance of pathological science.

The discoveries of Bouillaud, of Dax, and of Broca in relation to aphasia are among the most important in direct relation to hemiplegia; but having brought you to the time when apoplexy and hemiplegia have ceased to be names of diseases and are regarded as symptoms of some morbid condition which remains to be investigated, I propose to offer to you a few disconnected observations on subjects which seem to me at present deserving of further investigation in relation to varieties of hemiplegia.

I. *Aphasia*.—1. In the past year in St. Bartholomew's Hospital I had under my care a man aged sixty-three years who had an attack of fainting, followed by left hemiplegia. He was completely aphasic, but in two days had nearly recovered the power of speech and in a week had no defect either of speech or motion. When convalescent he amused himself as he sat up in bed by drawing portraits and caricatures of some merit, and always with his left hand. Sir George Paget published a case of aphasia with left hemiplegia in a left-handed man; but as such cases are sometimes open to the interpretation of multiple lesions, which mine, I think, was not, it seems desirable that more should be recorded. 2. Another point in relation to aphasia which seems to call for a careful collection of facts is the correlation of the patient's previous linguistic attainments with the degree of his loss of speech, and after death with the precise nature and extent of the lesion. In a family well known to me medically, and all of whom had an ability of expression considerably above the average, one member, a man nearly sixty, had an attack of right hemiplegia (undoubtedly due to embolus). He recovered so as to be able to walk and to use his right hand well, but continued aphasic to the end of his days. He had no verbal deafness. Before his attack he could speak and write four languages besides English—viz., French, Spanish, Portuguese, and Dutch. He knew all of them well—French, for he had resided for some years in an out-of-the-way part of France and had married a French lady; Spanish and Portuguese, for he had served in the Peninsula under Wellington, and had there commanded a Portuguese force; Dutch, for he had held an important office which took him into many parts of Cape Colony, and required him to be in constant communication with the Dutch residents there. Of all these tongues he was only, after his attack, able to use three words—*exactly*, which he used for assent (he shook his head for "no" and never used "yes"); *sea*, which he used to express or rather to suggest to his hearer any idea in relation to the numerous foreign countries in which much of his life had been spent; and *God*, which he used in relation to every kind of religious idea. He was able to write his name, but was otherwise agaphic. Once when he had in vain endeavoured to make some of his family understand what was in his mind he went down (in illustration of his thoughts) on his hands and knees and plucked some grass with his mouth. "You mean," said a clever sister, "that you feel like Nebuchadnezzar." "*Exactly*," he

replied, rose, and continued his walk with her. He had with his sisters learnt to dance in childhood in Portugal with a family—natives of Lisbon. One day while out walking with his two sisters, one of them said, forgetting his aphasia, "Do you remember the name of the family with whom we learned dancing in Portugal?" He smiled and shook his head. His sister affectionately apologised. They went on and his sisters talked together. They had been walking for some time when they passed, near a farmyard, an old iron pot lying on its side. He stopped them, and struck it with his stick. They did not understand. He waited and struck it again. Then he walked a few steps of a minute, and struck the iron pot again. His elder sister said, "You mean that Caldero (a cauldron in Portuguese) was the name of the family with whom we learned that dance." "*Exactly*," he replied. 3. It is a general and, I think, a well-grounded opinion that if some improvement does not take place early as regards aphasia there is unlikely ever to be much restoration of speech. John Locke, the philosopher, who was a Bachelor of Medicine of Oxford and who had given much thought to medicine, had observed this, as is clear from a passage in one of his letters in which he says that his experience is that if bleeding does not produce an improvement soon as regards speech it seldom does so at all. Precise observations as to the rate and degree of improvement in aphasia are much needed. 4. The close observation of the slight degree of verbal failure which sometimes follows fatigue, even in the young, is also a desideratum, as is the record of verbal habit. 5. Was the "Est-il possible?" of Prince George of Denmark, Queen Anne's husband, a mere reflex? If not, what was its remote connexion with any true idea? 6. Everyone knows how a boy, warned not to make a particular verbal error such as a false quantity, is liable from mere anxiety to avoid it (as it seems) to fall into it a second or even a third time. A series of precise notes on this subject would be valuable. 7. Finally, as regards speech, is it not worth the careful attention of the learned whether the regular variations included under the term of "Grimm's law" may not better be accounted for in relation to the third frontal convolution than as has hitherto been proposed in relation to the formation and muscular peculiarities of the larynx? In the same relation perhaps may lie the explanation of the varieties of syntax in the speeches of different nations. In English the verb usually follows its subject, in Gaelic it generally precedes it, in Latin it stands at the end of the sentence, and in German, when a full stop is at last reached, a preposition is often found to be the last word of all. Every family, every individual, has a peculiar language under the direction of a peculiar third frontal convolution. May not a constant variation and grouping of similar variations in that part of the brain be at least one factor of the idiom of expression of a race?

II. *Hemiplegia of children*.—This affection is no doubt sometimes not cerebral, but due to anterior poliomyelitis; but apart from cases due to cerebral tumour some examples are undoubtedly due to the same causes as adult hemiplegia—at any rate, to embolus, hæmorrhage, or gumma. I have never met with an example of the last post mortem in a child; but since I have found well-marked large gummata in the liver of a child, a condition of which several examples are recorded, there seems no improbability in a similar condition occurring in the brain of a child as it does in that of an adult. I once saw a child who had become hemiplegic (on the right side) about an hour before, after a violent fit of whooping-cough. I suspected the onset of tuberculous meningitis. The child was aphasic, but in a day or two some improvement appeared, and the patient ultimately lost all signs of paralysis, not rapidly, but in course of years, and the slight aphasia, which remained for some months, ultimately disappeared too. Was this condition due to superficial or capsular hæmorrhage or to embolus? I suspect the former from the extreme engorgement of the face during the cough. Cortical injuries during birth leading to hemiplegia are often spoken of, but both in this case and in that of the spastic paraplegia of children sometimes also attributed to such injuries I am inclined to doubt whether bruising of the cortex is likely to be an explanation of the symptoms. The children with spastic paraplegia are generally more or less mentally defective, and as regards the hemiplegia what an extensive and severe cortical injury would be required to produce it. Post-mortem evidence as to such cases is much needed. Some are perhaps due to arrested cerebral development: a hæmorrhage due to a scorbutic condition may account for others, embolus of course for some.

III. *Transient hemiplegia*.—This is an interesting symptom.

¹⁶ Aretæus (ed. F. Adams): Chronic Diseases, book i.

Hysterical cases are not very common, but I once saw a woman aged about twenty-six years who believed that she had just become hemiplegic. There were no facial or lingual symptoms, but her arm and leg seemed powerless. They were of unaltered temperature and reaction, soon recovered, and never became paralysed again. A child aged five years with a solid lung became hemiplegic, being at the time nearly unconscious and roused with great difficulty. Tuberculosis seemed imminent, but after a fortnight consciousness returned and the child slowly recovered. Was this due to a meningitis associated with the pneumonia? Whatever the cause its effects passed off completely.

IV. *Hemiplegia in tubercular meningitis.*—This does not necessarily indicate tumour. A man aged twenty-one years became suddenly delirious, having been in a febrile condition for a few days. He was admitted to St. Bartholomew's Hospital and in a few days more became hemiplegic on the left side, and continued so till his death. I examined him post mortem. He had no tumour, but tubercular meningitis with general tuberculosis throughout his body.

V. *Post-hemiplegic state.*—Lastly, how much room for interesting study is there of the state of patients after hemiplegia. "Nunquam tamen fuit ita subtilis ingenii et bone memorie sicut prius," says Mirfeld of the Canon after his cerebral injury. Let us recall, too, the Archbishop of Granada in "Gil Blas." Le Sage certainly described him from the life. The Archbishop, a famous preacher, desired Gil Blas, his secretary, to let him know if he ever noticed in him any signs of intellectual failure. The secretary almost doubted the possibility of such a thing, but the prelate insisted. "Je te le répète, Gil Blas, dès que tu jugera que ma tête s'affaiblira, donne m'en aussitôt avis." "Two months later he had a fit of apoplexy, from which he recovered in a few days "mais son esprit en reçut une rude atteinte." Gil Blas noticed the marked inferiority of the very first sermon the Archbishop preached after his recovery. Subsequent sermons were diffuse and wordy, quite unlike his former dignified oratory. Everybody noticed it. Gil Blas told him of it and was dismissed, for the Archbishop himself was sure that he was as great a preacher as ever and that it was his secretary whose ability was failing. Not only the failure of power of the patient after apoplexy, but his vanity—more obvious after than before the attack—are true to nature. In this period of the disease how great is sometimes the difference between the condition after hæmorrhage in the latter half of life and that after embolus in the earlier half of life. It is often the difference between a general disease and a local injury. The cerebral softening or hæmorrhage is merely the end of a series of degenerative changes, and when its immediate effect is over they remain. Sometimes a man whose daily work is intellectual struggles on after he has recovered, as we say, from a cerebral hæmorrhage. He may do some work, but in the cases which I have seen the work was never again of the best kind, never more than a reflection, more or less indistinct, of his past work. Uneducated men seem to bear such attacks better than educated ones, and I have seen cheerful and fairly vigorous out-patients who had a partially recovered hemiplegia, such as in an educated man would probably be associated with a seeming loss of all the sunshine of life. My own observation is that the weakness following hemiplegia, while it diminishes the creative and working power of all minds, has a much less deteriorating influence on patients of fixed principles and opinions than on those whose virtues are chiefly dependent on their surroundings and who have lived without ever considering or determining the problems of life.

In the prevention of such illnesses as hemiplegia due to softening or to hæmorrhage we have to impress upon our patients that, whatever the kind of toll exacted from the mind and body, most may be done by avoiding the doing in any day more than that day's strength is equal to, and that overstrain means diminished efficiency, sometimes at the moment, always if the whole working period of life be considered. I am thinking of useful work, but we must remember that the work with which men fatigue and wear out their tissues is not always useful work: feasts and deep potations, these are tolls which break down the blood-vessels and the brain, and of which we can at least advise our patients to consider the cost. Real work of mind and body, even if severe, takes less out of the frame than what may be called forced tissue change;

but if its limits are made clear to each man we shall do much to save him from hemiplegia.

The ancients had no clocks with hands, and their hours, which they named by the successive letters of the alphabet, were merely divisions, varying with the solstice, of the time between sunrise and sunset. ΖΗΘΙ were therefore afternoon hours, and hence the saying:

Ἐξ ὥραι μὲν θοοὶς ἰκανώταται: αἱ δὲ μετ' αὐτὰς γράμμασι δεικνύμεναι ΖΗΘΙ λέγουσι βροτοῖς.

(Six hours are enough for work: those that are marked by the letters ΖΗΘΙ say to mortals "LIVE.") With our advanced, if yet incomplete, knowledge of the functions and disorders of the nervous system and of the whole body, to maintain the doctrine of cheerful relaxation expressed in this proverb is one of our first duties as medical advisers. I hope that this address has not been so severe as to prevent your Medical Book Society's evening from being a relaxation, nor so light as to be undeserving of its attention.

THE SPOROZOA OF VARIOLA AND VACCINIA.¹

By J. JACKSON CLARKE, M.B. LOND., F.R.C.S. ENG.,
PATHOLOGIST AT ST. MARY'S HOSPITAL, AND ASSISTANT SURGEON
AT THE NORTH-WEST LONDON HOSPITAL.

It has been found that if a scratch is made in the cornea of a rabbit or a guinea-pig with the point of a sterilised knife, and then a little active vaccine lymph is laid on the scratch, cell infection occurs.² I have made the experiment seven times with a positive result in each case. What is understood by the term "cell infection" will be best conveyed by a detailed account of the histological changes which follow the inoculation. If the animal is killed forty-eight hours after vaccination and the cornea is at once excised and placed for twenty-four hours in a saturated solution of corrosive sublimate, and then prepared in the usual way, vertical sections show cell inclusions lying close to the nuclei of the deeper epithelial cells at and in the vicinity of the seat of inoculation. These cell inclusions are minute highly refracting bodies, which stain deeply with acid hæmatoxylin, but show a preference for such stains as carmine, eosine, and acid fuchsin. The appearance of one of the epithelial cells in a section stained with hæmatoxylin is shown in Fig. 1. Most of the cell inclusions are homogeneous, but some have in their dense substance a central denser spot. Many of the bodies give evidence of subdivision into two similar parts. Some of the cells contain two such bodies. There is nothing in the above-mentioned bodies which would exclude the possibility of their being due to some form of degeneration.³ The facts, however, that amoeboid movement has been observed in these bodies and that their presence is dependent upon previous vaccination point to their being intra-cellular parasites, and their peculiar density and high refractive index also agree with what I have described as features of certain sporozoa. If they are parasitic it is necessary to inquire to what group of organisms they may belong. The chief groups of unicellular parasites which pass part of their existence within the cells of their host are the chytridiaceæ, the synchytriaceæ, some of the suctoria, and the sporozoa. The chytridiaceæ are regarded as fungi devoid of mycelium. They occur in some algae and other plants. The synchytriaceæ, hitherto regarded as vegetable organisms belonging to the chytridiæ, are now considered by Zopf⁴ as

¹ The literature relating to this subject is given fully by L. Pfeiffer in *Behandlung und Prophylaxe der Blattern*, Jena, 1893; reprinted from the *Handbuch der Specieellen Therapie*, edited by Penzoldt and Stintzing. It should be added that Lionel Beale described the amoebæ of Van der Loeff in the *Quarterly Journal of Medical Science*, vol. iv. (old series), but without suspecting their parasitic nature.

² Guarnieri, led by the observations of Van der Loeff and L. Pfeiffer, was the first to test and demonstrate this fact, and at the same time to confirm the earlier descriptions of L. Pfeiffer, who soon confirmed Guarnieri's observations, and added a detailed description of the movements exhibited by the intra-cellular parasites in the presence of weak methyl-blue solution.

³ Cohn (1872), Weigert (1874), Pohl-Pincus (1882), Planth (1883), Leloir (1880), Unna and Burri (1892), L. Pfeiffer points out, have previously described these bodies under various names in variola and vaccinia, sheep-pox, varicella, and herpes zoster.

⁴ W. Zopf: *Beiträge zur Physiologie und Morphologie niederer Organismen*, Heft 3. Leipzig, 1893.

¹⁷ *Histoire de Gil Blas*, vol. iii., p. 140. London, 1782. (This volume was first published in 1724.)

probably belonging to the protozoa. This view would approximate them to the two remaining groups. They are parasitic in many plants. Some of them have flagellate swarm spores. The common acinetæ may be given as an example of the suctoria, some species of which enter the bodies of other protozoa and there subdivide into ciliated spores. It may prove that they are linked to the sporozoa by intermediate forms. As far as is known they are confined to other protozoa as hosts. The sporozoa are probably most nearly related to the ciliata, and are necessary parasites. They are met with in the metazoa from the tapeworm upwards. The name of the group was derived from the

FIG. 4.—Intra-cellular parasite with central reticulated zone. Same source.

FIG. 5.—Epithelial cell containing a group of small bodies resulting from the subdivision of an intra-cellular parasite.

FIG. 6.—Three free parasites. Two have a well-marked "peripheral granule layer," the third is club-shaped. Same source.

FIG. 7.—A large free parasite undergoing subdivision into spores. Same source.

Acid hæmatoxylin and eosine staining. The bodies were drawn with a Zeiss's $\frac{1}{2}$ in. immersion lens, for the loan of which I am indebted to the Scientific Grants Committee of the British Medical Association. I also wish to thank my friend Mr. A. F. Bill for the loan of a Zeiss's stand and lenses.

hard-shelled bodies known as pseudo-navicellæ, the sporocysts of certain gregarines. In some of the sporozoa, for instance, the sarcosporidia and the so-called psorosperms of the human urinary tract,⁵ hard-shelled spores (sporo-cysts) have not been met with, and thus the name of the group is no longer completely applicable. Similarly, sickle-shaped spores are not a necessary phase. They are absent in the myxosporidia, the microsporidia, &c.

The decision of the position in classification to be assigned to any newly described organism must ultimately rest with

biologists; but since for the past three years I have devoted most of my leisure to the study of the comparative morphology of intra-cellular parasites I may perhaps be permitted to express my view of the bodies I am now considering and to give the basis on which that view rests. The few features already sketched would certainly not suffice to refer the bodies either to the protophyta or the protozoa. The vaccinated cornea at the end of the third day is admirably suited to afford additional evidence, which consists in the presence of a variety of organised structures constituting an extension of the series shown in Fig. 1. Thus, besides the small parasites, such as are represented in Figs. 2 and 3, others similar to that shown in Fig. 4 appear with a central reticulated zone.⁶ There is also evidence that these cell inclusions break up into highly refracting segments. An instance of this is shown in Fig. 5. This intra cellular group of bodies I regard as the result of subdivision rather than of multiple infection on account of their arrangement, staining reactions, &c.⁷ The gradation of forms already portrayed not only favours the supposition that the bodies are parasitic but that they belong to the sporozoa. If this is the case there should be present, besides the intra-cellular bodies, ripe or adult parasites which have escaped from their host cells and lie free on the surface or in the interstices of the epithelium, for all the known sporozoa without any exception when infesting epithelium present such free bodies. Free parasites, as I may now justly term them, abound in the vaccinated cornea on the third day. Some are in the form of large round, oval, or pear-shaped (Fig. 6 to the right) cells of the same general characters as the bodies I have described as free sporozoa in cysts of the ureter and various cancers and sarcomata; they have a central granular portion surrounded by a dense ectosarc.⁸ Others of the free parasites present an appearance characteristic of sporozoa—namely, a clear central part bounded by a distinct zone of granules.⁹ Two parasites with this peripheral granule layer are shown in Fig. 6 to the left. Lastly, I will mention large free parasites which have evidently undergone subdivision into segments some of which are granular, others possess nuclear matter either in the form of fragments or radiating bars. Such a body is shown in Fig. 7.¹⁰ After the most careful consideration I have come to the conclusion that the larger segments of such bodies may be taken to represent sporogonia, and the smallest spores.

Such an extended series of forms fully warrants the conclusion that the bodies are parasitic and justifies our placing them, at least provisionally, among the sporozoa. The bodies described above as sporozoa present the most complete homology with bodies I have described also as sporozoa in cancer¹¹ and sarcoma. The invasion of leucocytes in the vaccinated cornea begins on the third day. There is nowhere the least ambiguity between leucocytes and parasites. Appearances which may be construed as phagocytosis are present, but not very abundant.

Dr. T. F. Ricketts kindly afforded me an opportunity of examining the contents of variola vesicles and the skin of persons who had died from small-pox. In both situations I was able to find bodies identical in structure with those I have described above in the vaccinated cornea. Until the nature of these structures is settled, and the minds of pathologists are familiar with their presence and meaning, it would be premature, perhaps, to discuss the question of the relation of the parasites to variola and vaccinia. I may, however, refer to the importance of the observations made

⁵ This figure may be compared with the cell inclusions figured by me in squamous epithelioma (Morbid Growths and Sporozoa, Figs. 6 and 7), and in cancer of the breast (Ibid., Fig. 27).

⁷ With this may be compared the condition I have shown in squamous epithelioma (Ibid., Fig. 8).

⁸ These are the bodies I referred to as probably free sporozoa in vaccine lymph (Medical Press and Circular, Sept. 6th, 1893). L. Pfeiffer has pointed out that these large free bodies show amoeboid movement on the warm stage; thus they are distinguished from degenerated cells.

⁹ I was the first in this country to describe such bodies as cell inclusions in cancer, and to point out their significance (Medical Press and Circular, Sept. 28th, 1893).

¹⁰ This body is to be compared with that figured by me in squamous epithelioma (Brit. Med. Jour., Dec. 24th, 1892).

¹¹ My conclusions with regard to squamous epithelioma have been confirmed in certain particulars by Koromeff (Centralblatt für Bakteriologie, March, 1893) and Kurloff (Ibid., March, 1894). Shron of Naples, like the author, regards certain bodies in mammary cancer as parasites (International Congress, Rome, 1893). Miller (Congress of Physicians, St. Petersburg, noticed in Centralblatt für Bakteriologie, April 7th, 1894) confirmed my view of certain bodies in uterine cancer. Pawlovsky (Virchow's Archiv, September, 1893) and Vedeler (Centralblatt für Bakteriologie, 1894) have fully confirmed my work on Sarcoma.

⁶ Jackson Clarke: Transactions of the Pathological Society, 1892.

by Van der Loeff and L. Pfeiffer as to the motile flagellate bodies in the blood of persons suffering from these diseases. I will close these brief remarks by stating that in my opinion the processes which take place in the vaccinated cornea and in other lesions of vaccinia and variola are comparable in a remarkable degree to those which I have observed in cancer. The parasites in the latter condition present a more extended series of forms than those of variola; yet in both cases the fundamental characters of the parasites are the same—namely: "At certain stages they resemble recognised sporozoa, the intra-cellular phases being of especial importance. They tend to assume a round or oval form. Their protoplasm is dense and highly refracting and stains deeply with carmine, acid fuchsin, &c. Their nucleus often does not give the reaction of chromatin to acid hæmatoxylin. All stages of swarm-sporing can be observed."¹² Moreover, the same hypertrophy of cell protoplasm and cell nuclei is seen in the vaccinated cornea and in various cancers and sarcomata.

Old Cavendish-street, W.

NOTE ON THE LOCALISATION OF TACTILE IMPRESSIONS IN THE BRAIN.

By EDWARD C. SPITZKA, M.D.,

PRESIDENT OF THE NEW YORK NEUROLOGICAL SOCIETY, LECTURER ON MEDICAL JURISPRUDENCE AT THE POST-GRADUATE MEDICAL SCHOOL, PHYSICIAN TO THE DEPARTMENT OF NERVOUS DISEASES OF THE METROPOLITAN THROAT HOSPITAL, ETC.

THE careful deductions of Exner have, in great measure, bridged over the chasm existing between the radical "localisationists" and the so-called "anti-localisationists." On the one hand, the general principle of localisation has been shown to be correct by the Vienna observer; on the other hand, that narrow limitation of numerous centres to areas not exceeding a few millimetres in diameter, which has constituted such a vulnerable position for the onslaughts of Goltz and Brown-Séquard, must now be considered untenable. Just as the fibre masses of the corona radiata are seen to spread out fan-shaped, and while terminating chiefly in some special cortical districts, yet detach scattered fibres to neighbouring areas, so the fields of cortical function delineated by Exner in his great work¹ are shown to consist of "absolute" and "relative" fields. The former have a constant relation to a given function; the destruction of the "absolute" field for the muscles of the arm is always followed by paralysis of those muscles. The latter have an inconstant relation; the destruction of the "relative" field of the arm muscles which surrounds the absolute field in zones of gradually diminishing intensity sometimes leads to such paralysis and sometimes does not. The various fields of motor and sensory function are also noticed to overlap considerably; the field for the arm dies out within the visual area, and encroaches considerably on the speech field. But a most interesting result of Exner's laborious compilation and comparison of the numerous cases of limited cortical lesion scattered through modern neurological literature is his conclusion that, as a rule, the sensory fields are nearly identical with the motor fields for the same periphery, and he cites this as a remarkable confirmation of the experimental results of Munk, who found his tactile areas in the dog's brain to correspond with the motor areas of Hitzig and Fritsch. Not only do the tactile fields correspond very closely to the motor fields of the same body regions, thus sustaining the anticipation of Meynert that the rôle of the cortex is not so much the liberation of an explosive motor force as the mediation of sensations of innervation (*Innervationsgeföhle*), but all determinable function areas which on physiological grounds must be considered to require a bond of association in the cerebral mechanism are found to have a regional contact. Thus the symbolic field, that devoted to the registration and liberation of spoken and written symbols, is found to approach the fields of the upper extremity and of the lingual and auditory peripheries.

While our knowledge of the sensory cortical area is daily becoming more satisfactory, that of the course of the sensory tracts connected with the cortical areas in question is very

imperfect. We know partly from Veyssièr's experiments, and partly from confirmatory pathological observation, that the fibres conveying tactile impressions are chiefly concentrated in the posterior division of the internal capsule. Meynert,² whose anatomically based presumptions have in many respects anticipated the results of actual observation, entertained the belief that this portion of the internal capsule was continued in the outer third of the pes pedunculi, the descending pyramidal tract, and reached the posterior columns of the cord through his so-called "upper fine-bundled decussation of the pyramids." On Meynert's hypothesis, then, the connexion between the posterior and "sensory" columns of the cord and the posterior part of the internal capsule was clear. Flechsig,³ however, showed that the true pyramidal tract has no connexion with the so-called upper decussation, and the conclusion was somewhat hastily drawn that Meynert's theory of a connexion between the posterior columns and the cerebral hemispheres was to be abandoned. In reality, Meynert's hypothetical tract requires but two topographical modifications to accommodate it to what is to-day demonstrable in any series of transverse and longitudinal sections of the brain isthmus.⁴ In a transverse section of the medulla oblongata, immediately above the level of the decussation of the crossed pyramidal tract, the raphe of the oblongata is seen to be very much thickened and to consist of fasciculi crossing at a rather acute angle. From the resemblance of the swollen part of the raphe to a fir-cone, whose knobs are represented by the entering fasciculi, I have proposed to designate this—which is identical with Meynert's so-called upper or sensory decussation—the piniform decussation.⁵ (Fig. 1)

FIG. 1.

B, Same of column of Burdach. S, Gelatinous nucleus of ascending trigemini root. F, Fibres from posterior column and its nuclei to piniform decussation.

Its fibres can be distinctly traced from the posterior columns, fielding off the grey masses of the nuclei of Goll's and Burdach's columns; they cross in the decussation and enter the internal division of the reticular field, dorsad⁶ of the pyramids, laterad of the raphe and mesad of the olive. Other of these fibres run into the hilus of the olive and in between the latter and the inner accessory olive constituting the lemniscus tract. I am not able to differentiate between the fibres which have these different destinations, though it

³ Leitungsbahnen &c.

⁴ Under this term I include the axial parts of the brain; in other words, everything not comprised in the cerebral hemispheres and the cerebellum.

⁵ Architecture and Mechanism of the Brain, Journal of Mental and Nervous Diseases, 1881.

⁶ Professor Burt G. Wilder's toponomical terms are used in this paper.

¹² Jackson Clarke: Morbid Growths and Sporozoa, p. 23.

¹ Untersuchungen über die Localisation der Functionen in der Grosshirnrinde des Menschen. Braumüller, Wien, 1881.

seems that the fibres from the column of Goll mainly go to the field situated between the raphe and olive and dorsad of the pyramid, which is continuous with the stratum intermedium of the pons levels. The stratum intermedium, thus named by Meynert because it lies between the derivative tracts of the pes pedunculi and tegmentum and described by Henle as the "Bündel vom Fuss zur Haube," has been much neglected by anatomists. A careful embryological and comparative anatomical study of this tract cannot fail to throw much light on the cerebral architecture and we would refer provisionally to its enormous preponderance in the elephant, in which animal it appears to have different

FIG. 2.

attributes than in man, evidently taking the place of the pyramidal tract, which in this animal is not present, at least in its typical relations, though the pes pedunculi is well developed. The fibres of the stratum intermedium enter the pes pedunculi in its inner third, and constitute one of the deeper fields of the pes described by Flechsig subjacent to the ganglion of Soemmering (substantia nigra). In the course of the imperfect spiral twist of all the pes fibres this field gradually moves to the outer part of the pes, and consequently becomes the most posterior portion of the internal capsule. Meynert's hypothetical tract may be thus re-established by

FIG. 3.

changing the nomenclature of the sensory decussation and substituting "stratum intermedium" for "outer part of the pyramidal and peduncular tracts." No uncomplicated lesion of this tract is recorded in the literature of focal brain lesions. I have been fortunate to observe one case since I first proposed the rehabilitation of Meynert's theory with the modifications here laid down,⁷ and as far as it goes the deductions to be drawn from it coincide remarkably with the anatomical theory. As I propose to publish the case in full when the microscopical analysis shall have been completed, I will here mention only the salient points. A man with moderate indications of atheromatous degeneration of the vascular system had had a sudden "seizure" while straining at stool, accompanied by complete right hemianæsthesia. I examined him two years after the attack, and found that the tactile sense had improved, but not to such an extent as to permit the man to resume his vocation; he had lost the faculty of

mechanical coördination without losing the sense of equilibrium or resistance. As there was contra-lateral facial palsy and marked difficulty of speech, approaching anarthria in its character, I diagnosed a hæmorrhage of the pons. Two years before his death he had another seizure of a transient nature, and several lesser ones followed at irregular intervals, the patient dying with terminal symptoms of paraplegia and amblyopia. A number of recent necrotic and cicatrised foci, with several very small hæmorrhages, were found in various portions of the brain; an old pigmented cicatrix was found replacing the right stratum intermedium, and involving the facial nucleus, ending at the raphe.

When it is borne in mind that those centripetal fibres which partly derived from Flechsig's direct myelo-cerebellar tract, and partly from the posterior columns through the olivary decussation, run into the cerebellar hemispheres, and that from the latter the transverse pons fibres originate, to apply themselves to the pyramidal tract and ascend to the brain through the pes pedunculi, it must be apparent that the great sensory tract united or nearly so in the cord, and widely separated in the oblongata and pons, becomes reunited in the pes pedunculi. This relation is best expressed in the diagram Fig. 4. Inasmuch as the sensory tract separates into two

FIG. 4.

Diagram of the tactile and equilibrium tracts. a, Tract from posterior column through piniform decussation to posterior part of internal capsule. b, Tract from posterior columns through decussation of olivary fibres to cerebellum, thence through pons to frontal lobes and great ganglia. c, Direct myelo-cerebellar tract. d, Auditory fibres to dentated nucleus and connexions. t, Its continuation to tegmentum.

divisions—one running directly through the brain axis to the posterior capsule, the other deviating from the direct course to enter the cerebellum, which ganglion mediates as a connexion of auditory and posterior column fibre—it seems legitimate to assume that the former division is the tactile and the latter the equilibrium sensation tract. Many doubtful points in the study of ataxic phenomena become clear in the light of this conclusion, particularly the common observation that there is no essential relation between tactile insensibility and ataxia. Another interesting point to

⁷ Chicago Medical Review and New York Medical Record, 1891.

determine is the anatomical connexion between the posterior columns and the trineural fasciculus.⁸ The trineural fasciculus originates in the plexiform decussation; whether its fibres are ultimately derived from the opposite posterior column, and hence connect the posterior columns and the great visceral cranial nerves, or whether they run up into the opposite stratum intermedium, it is difficult to determine. While I am inclined to believe that the latter is the case, the possibility of the former disposition must not be lost sight of. If it becomes established it will explain the remarkable effect which progressing disease of the posterior columns has on the production of gastric, bronchial, and cardiac crises.

TEN CASES OF DIPHTHERIA TREATED WITH ANTITOXIN.

By NESTOR TIRARD, M.D., F.R.C.P. LOND.,
PHYSICIAN TO KING'S COLLEGE HOSPITAL AND TO THE EVELINA
HOSPITAL FOR SICK CHILDREN;

AND

FREDERICK WILLCOCKS, M.D., F.R.C.P. LOND.,
PHYSICIAN TO CHARING-CROSS HOSPITAL AND TO THE EVELINA HOSPITAL
FOR SICK CHILDREN.

THE following cases of diphtheria have been under our care at the Evelina Hospital for Sick Children, where we were able to set apart a small isolation ward for their reception, and were fortunate in having a supply of Behring's antitoxin for their treatment. After our third case the supply failed us for a time, and it will be seen that the fourth case was treated with Aronson's antitoxin. A fresh supply of Behring's antitoxin was then received, and the remaining six cases were treated with it. In all the patients the treatment was commenced directly after admission and after a diagnosis had been made, partly on the appearance of the membrane and partly on the amount of depression, and in six of the ten on the small amount of albumen found in the urine. In some of them bacteriological investigations were also made. Two of our cases necessitated tracheotomy. In the first case tracheotomy was performed immediately after admission owing to the urgency of the symptoms; in the other case respiration stopped suddenly while some membrane was being obtained for examination and prolonged artificial respiration was necessary after the trachea had been opened. In the single fatal case death ensued after vomiting a quantity of blood, and the post-mortem examination revealed erosion of a branch of the tonsillar artery. With regard to the symptoms following the employment of antitoxin we noted rapid detachment of membrane and great improvement in the pulse and also in the general condition of the patients. In the fatal case the pulse was weak throughout, and in another case convalescence was marked by an abnormally slow pulse, which, however, improved after the administration of stimulants. This child also exhibited a rash somewhat resembling urticaria, but it was only present for a few hours. The last case treated developed urticaria, which gradually faded after three days. The albumen in the urine was not due to the antitoxin; it was detected in five cases before the treatment was commenced, and in a sixth (Case 1) it was found as soon as a specimen could be procured after tracheotomy. The amount of albumen was small in most of the cases, and it disappeared entirely before the patients left the hospital. It is too soon yet to say much about other sequelæ. So far as our present information goes, in none of our cases have any forms of post-diphtheritic paralysis appeared. Our cases have received the utmost care from our resident medical officers, Mr. W. L. Wainwright and Mr. T. Waddelow Smith, to whom we are indebted for the following abstracts of the notes:—

CASE 1. Tracheotomy; recovery.—A badly nourished boy five years of age was admitted to hospital on Nov. 3rd, 1894, in an apparently moribund condition, with extreme dyspnoea

and only occasional attempts at respiration. Tracheotomy was performed at once, followed by artificial respiration. The respiration became in a short time fairly good, but large quantities of foul-smelling mucus poured from the trachea. Both tonsils were covered with whitish membrane, and there was much offensive nasal discharge. The glands were much enlarged and there was one-tenth albumen in the urine. The disease was of ten days' duration according to the mother's account. The pulse after operation was 144, the respiration 48, and the temperature 102° F. Behring's No. 2 solution (10 c.c.) was injected at once. The pulse remained about 140 for two days and the respiration from about 36 to 40, but there was rapid and marked improvement in the heart sounds. On the afternoon of Nov. 4th the child was well enough to look at a picture book of his own accord. Large quantities of mucus and several pieces of membrane continued to be coughed up, and the temperature remained between 99° and 100°. On Nov. 6th the throat was quite clean, though still oedematous, the pulse was 120 and full, the respiration 28, and the temperature normal. The tracheotomy tube was removed on the same day, and recovery was quite uneventful, except that a fine trace of albumen remained until the 13th. On the 27th the patient was discharged in excellent condition.

CASE 2. Death.—A girl aged eight years was admitted on Nov. 7th, 1894, with diphtheria of two days' history. The tonsils were much enlarged and covered with membrane, as also were the soft palate and uvula. There were great pain on swallowing, profuse sanious nasal discharge, and much swelling on both sides of the neck. The pulse was 140 and very feeble, the temperature 101° F., and the respiration 36. Ten cubic centimetres of Behring's No. 2 antitoxin were injected. The urine contained one-twelfth of albumen. The pulse improved a little and fell to 120. The respiration was 23, and the temperature 98°, but the throat did not improve and the glands increased in size. On Nov. 9th, 10 c.c. of Behring's No. 1 serum were injected. The pulse remained about 120 to 130, but became more feeble, and the first sound could scarcely be heard at the apex. The nasal discharge increased, and though the temperature remained normal, the patient became very cold and the skin clammy. On the 10th she three times vomited a quantity of laminated clot, which appeared to have been lying in the œsophagus for some time and was of a greyish colour. On the afternoon of that day the patient gave a sudden convulsive start and died suddenly, a quantity of black coffee-ground material pouring from the mouth.

Necropsy.—There was very deep ulceration of the tonsils, and the right tonsillar artery was found to be laid open at the base of an ulcer for a distance of one-twelfth of an inch. There was a good deal of blood in the stomach, and the tissues in the submaxillary region were full of extravasated blood.

CASE 3. Large patch on tonsil; recovery.—A boy aged six years was admitted on Nov. 10th, 1894, with diphtheria of five days' duration. He was a well-nourished boy with a good family history. There was slight congestion of the tonsils and soft palate, and on the right tonsil there was a large grey patch of membrane. The uvula was clean, but slightly oedematous, and there were enlarged glands in the submaxillary region. The pulse was good, full, and strong, and 96 per minute; the respiration was 32 and not impeded; and the temperature was 104° F. There was no albumen in the urine. Two hours after admission 10 c.c. of Behring's antitoxin were injected into the muscles of the thigh. Three hours later the pulse was 108, the respiration 26 and the temperature 102°, the patient feeling very well. Six hours later the membrane had become almost detached, the patient still feeling very well. Next morning the pulse was 100, the respiration 24, and the temperature 98°. The patient took a hearty meal and did not complain of any pain in the throat. There was no albumen in the urine and the throat had completely cleared. The patient was discharged on the sixth day, being practically well.

CASE 4. Naso-pharynx; recovery.—This patient aged ten years was admitted on Nov. 16th, 1894, suffering from a moderately severe attack of diphtheria. The history was of seven days' illness, with sore-throat and general malaise. On admission the pulse was 120, the respiration 28, and the temperature 101° F. There was no albumen in the urine, and the general condition of the child was good. The throat was congested, both tonsils were enlarged and there was on each a small whitish patch of diphtheritic membrane, but none on the uvula or soft palate. There was considerable

⁸ "Solitary bundle" of Lenhossek and Stilling, *fasciculus lœres* of Lockhart Clark, "Respirationshindel" of Krause; I term it "trineural fasciculus" on account of its established connexions with the eleventh, tenth, and ninth (and that aberrant branch of the ninth pair, the *nervus inter-actius*) cranial pairs.

sanious discharge from the nose. Two hours after admission twenty minims of Aronson's antitoxin were injected into the subcutaneous tissue of the abdomen. Six hours later the pulse was 120, the respiration 36, and the temperature normal. The general condition was excellent. The next morning the pulse was 108, the respiration 24, and the temperature 97°; but there was still a slight patch on the tonsil, with soreness of the throat. After this the patient made a rapid recovery, and was discharged on the sixteenth day after admission practically cured. Besides the antitoxin treatment, a gargle of chlorine was applied locally in this case.

CASE 5. Severe; naso-pharynx; recovery.—The patient aged seven years, a well-nourished child, was admitted on Dec. 6th, 1894, suffering from a severe attack of diphtheria. The symptoms had been noticed for about three days. On admission the pulse was 140, small, weak, compressible, and very irregular; the respiration was 38, greatly embarrassed; and the temperature was 103° F. The throat was greatly swollen and the patient complained bitterly of pain on swallowing. There was a trace of albumen in the urine and a well-marked fetid discharge from the nasal cavity. On the right tonsil there was a complete layer of a whitish-grey membrane, which did not reach to the uvula or soft palate. On the left tonsil there was a smaller patch. The glands at the angle of the jaw were also enlarged. Soon after admission 5 c.c. of Behring's No. 1 solution were injected into the abdominal wall, but with slight effect, the pulse being 140, the respiration 34, the temperature remaining elevated, and the general symptoms increasing in severity. On the following day, the throat symptoms having become much worse, with great dyspnoea and marked signs of laryngeal obstruction, and the pulse also being very weak, compressible, and irregular, 10 c.c. of No. 2 Behring's solution were injected; this produced marked improvement, the pulse being reduced in four hours to 108 and becoming more regular, the respiration to 32, with less dyspnoea, and the temperature to 99.4°. The next morning the membrane on the throat, which had greatly spread, was nearly detached, the pulse being 120 and much stronger, and the respiration 32, easy, and quiet. The child became quite convalescent and developed no bad symptoms. A chlorine gargle was also used in this case, but antitoxin was the only medicine given.

CASE 6. Tonsil and uvula, recovery.—The patient aged three years and nine months was admitted on Dec. 10th, 1894, with sore-throat of five days' duration, which was rapidly getting worse. The throat was congested, the uvula cedematous, and there was a patch of whitish membrane on the left tonsil. There was a faint trace of albumen in the urine. The temperature was 104° F., the respiration 28, and the pulse good (134). On the patient's admission 10 c.c. of Behring's No. 1 solution were injected, and six hours later the pulse was 120, the respiration 18, and the temperature 98°. Next morning the throat was quite clean and the general condition excellent. Since then there has been uninterrupted recovery.

CASE 7. Both tonsils; recovery.—The patient, aged two years and eight months, was admitted on Dec. 17th, 1894, suffering from an attack of diphtheria of twenty-four hours' duration. On examination he was found to be a well-nourished child. The pulse was 144, small, and compressible, but quite regular; the respiration was 44, deep and easy, with no adventitious sounds in the chest; and the temperature was 104° F. A faint trace of albumen was found in the urine. Both fauces showed well-marked congestion, with, on the right tonsil, a mass of thick, tough, greyish-white membrane about the size of a sixpenny piece, and on the left tonsil there was a smaller but well-defined patch of the same character. Ten cubic centimetres of Behring's No. 1 solution were injected on the patient's admission, and the throat was swabbed and sprayed with a chlorine water gargle. Three hours afterwards the pulse was 132, fuller, and less compressible, the respiration 32, and the temperature 100°. He slept well during the night and did not complain of any tenderness when swallowing. The following morning the pulse was 120, the respiration 26, and the temperature 99°. The child was looking bright and happy. The membrane on the throat had not spread, and was becoming detached on the edges and of a greyish colour. The same night the pulse had fallen to 100, being good and full. The temperature was normal and the respiration 24, the general condition being excellent. The albumen had disappeared from the urine. Patches were still to be seen on the tonsils, but were rapidly disappearing. Twenty-four hours later the

pulse was good, varying between 100 and 110, the respiration 24, and the temperature still normal. There were no patches to be seen on the throat. The child was apparently quite convalescent and taking with relish full diet. The bacteriological cultivations from the throat showed a large number of streptococci and staphylococci, with a few well-defined diphtheritic bacilli.

CASE 8. Soft palate and tonsil; tracheotomy; recovery.—The patient aged five years was admitted on Dec. 19th, 1894, and was said to have been ill for nine days. At the time of admission the child was very cold and cyanosed, with scarcely perceptible pulse and much dyspnoea. The pulse was 144, the respiration 36, and the temperature 97.6° F. The lower ribs were being sucked in violently. The soft palate, uvula, and right tonsil were covered with membrane, and the cervical glands were much enlarged. Ten cubic centimetres of Behring's No. 3 antitoxin serum were injected at once. While taking a cultivation from the throat the breathing became suddenly absolutely obstructed, and the child in a moment was flaccid and made no attempt at respiration. Tracheotomy was performed with a single incision, and after several minutes' artificial respiration some attempt at breathing became manifest, and in about fifteen minutes full respiration was restored. An hour later the pulse was 120, the respiration 28, and the colour good. The urine contained about one-thirtieth albumen, the heart dilated moderately, and the lungs were healthy. There was profuse discharge from the nose. The child slept well all night, the breathing being easy and quiet, with little coughing. In the morning the pulse was 144, being fairly good, the respiration 36, and the temperature rose to 101°. Food was well taken. The membrane had cleared off the tonsil, but remained on the uvula and edge of the soft palate. At 9 A.M. the pulse was 120, the respiration 26, and the temperature 100°. The colour was good. The child was well enough to play with toys and look at a picture book. At 9 P.M. the pulse was 124 and the respiration 28. The discharge from the nose had almost ceased. A good deal of tenacious mucus was being coughed up, but no membrane, and the throat looked less swollen and showed less membrane. The cervical glands were much less swollen. The child slept well. The heart sounds were good and the patient was apparently quite comfortable. The cultivations showed Löffler's bacillus and a few cocci. The child subsequently convalesced rapidly with no bad symptoms.

CASE 9. Diphtheria with pertussis.—A child aged six and a half years, suffering from pertussis, on Dec. 21st developed feverish symptoms with soreness of the throat. The pulse rose from 120 to 140, respiration from 20 to 40, and the temperature from normal to 104° F. There were vomiting and general malaise, and on examination of the throat it was found to be covered with diphtheritic membrane. The glands were enlarged, but there was no albumen in the urine. Ten cubic centimetres of No. 1 Behring's solution were injected, with the result that the temperature fell to normal in six hours and the feverish symptoms subsided, the child making a rapid and uninterrupted recovery. Bacteriological examination showed diphtheritic bacilli in large numbers, but few cocci.

CASE 10. Tonsils; soft palate; rash.—A child aged four years was quite well and attending school the day before admission, but that same night complained of pain in the throat, vomited, and seemed generally feverish. When seen on the day of admission, Dec. 24th, 1894, the patient was a well-nourished child with marked dyspnoea and slight cyanosis, enlarged glands at the angle of the jaw, and some cellulitis of the neck. The tonsils were enlarged and covered with typical diphtheritic membrane, which also extended to the uvula and soft palate. There was no nasal discharge. The temperature was 101.4° F., the respiration was 20, and the pulse was 120, weak, and very compressible; the urine (sp. gr. 1015) contained no albumen, and no urates in excess. Ten cubic centimetres of No. 1 Behring's solution were injected deep into the muscles of the thigh, and three hours afterwards the temperature had fallen to normal, the respiration was 24, and the pulse 120, but fuller. The next morning the patient's dyspnoea had quite disappeared, and the membrane was rapidly becoming detached from the throat; there were no bad symptoms. The following day an urticaria was noticed extending from the site of puncture rapidly over the body, but giving apparently no discomfort to the patient, whose general condition was excellent. Bacteriological examination showed a large number of diphtheritic bacilli.

SOME CASES OF GRAVES' DISEASE, SUCCEEDED BY THYROID ATROPHY.

By W. W. BALDWIN, M.D.

In reporting the following cases I desire simply to record the doubts and perplexities of a busy general practitioner in the presence of strange disease processes. I shall be quite content to have succeeded in relating the facts briefly and clearly, exactly as they occurred, without generalisation. I anxiously realise how difficult and ambitious a task it is to accomplish, but I venture to hope that I have not utterly failed to eliminate the deceptive note of personality and prejudice.

The case which I will first report seems unique, considering the youth of the patient and the comparatively rapid cycle of pathological change. The mother, a very poor but intelligent mountain peasant, brought her lad to me on July 26th, 1893, "not on account of illness, but because he was good for nothing, and perhaps the doctor might be able to rouse him." The lad was one of the heaviest, dullest overgrown boys of ten years of age imaginable, mostly half asleep. He would doze off sitting or standing, like the fat boy in the "Pickwick Papers." His skin was pale, dry, and inelastic, the connective tissue under the eyes loose and baggy, the face broad and flattened, and the hands big and puffy. He had a large, pendulous double chin, his great mass of coarse coal-black hair was dry and brittle, and the cheeks were notably scarlet, as though painted. The temperature was 97° F., the heart's action slow and lagging (55), its sounds were normal although its apex beat was displaced downwards and outwards about half an inch (the probable cause of this hypertrophy of the left ventricle will appear later), and the respiration was slow and deliberate. The liver and spleen were not enlarged, nor were any enlarged lymphatic glands discovered, although the boy was stripped and carefully examined from head to foot. The urine was normal. The appetite was moderate, there was no indigestion, and the bowels were regular. The mother related that several years previously he had suffered from palpitation and breathlessness, swelling of the neck, and prominence of the eyes, that he had also been extremely nervous and sleepless at that time, and it was thought he had heart disease. She "knew that he had been perfectly well until six years of age, and that he first began to swell and resemble the ox about two years ago." My friend, Dr. Milani, an experienced local practitioner of the neighbouring commune, who had referred this boy to me, had never seen a case of cretinism in the region of La Traversa, a primitive mountain resort in the Tuscan Apennines, where I was spending my summer vacation. He had seen this patient from time to time during the heart attack, and assured me that it had been a typical case of Graves' disease. It must be confessed that we were both puzzled as to where the pendulum had swung in this particular pathological clock. An extemporaneous examination of the blood showed a certain diminution of red corpuscles, and acting upon this hint the treatment adopted was regulation of diet and hygiene, with appropriate doses of iron and arsenic. I might add that the patient had been living upon vegetable soup, now, and then a bit of cheese, sparingly of sour bread and potatoes, but chiefly upon polenta or ill-cooked maize-meal porridge, without wine. An experimental repast of this inhuman mush had given me a woful indigestion, with such heaviness and mental inhibition as influenced me, no doubt, in forming an opinion of this boy's condition. I seemed to feel just as he appeared. I would say that we furnished him chicken, eggs, milk, a little meat, certain green vegetables and fruit, rice and macaroni, with a moderate allowance of good red wine. The above treatment was continued until Aug. 17th, but without the slightest appreciable effect. At this time a generous provision of various medicaments and drugs arrived from London. Among these was a stock of five-grain tablets of dry thyroid gland powder. It then first occurred to me that our youthful patient had played the gamut of thyroid change in four years, and was now suffering from atrophy and consequent myxœdema. These tablets were now administered. It was found that four daily were well borne, but a larger dose caused palpitation and breathlessness. Strangely enough, the mother remarked when this occurred, "My boy

acts just as he did when he had heart disease." The effect of this treatment was markedly favourable from the first, although the improvement was neither so rapid nor so brilliant as in some cases of uncomplicated myxœdema for which I had prescribed the same preparation. The patient came to see me every second day until Sept. 18th, when I returned to Florence. At this time he was more eager and alert, the general puffiness had almost disappeared, the pulse was 70, and the temperature 98°. The boy actually seemed a size smaller. My friend, Dr. Milani, one of the Good Samaritans of the Apennines, then gladly undertook the case, and in his last line of news, March, 1894, he said: "Our patient is perfectly well, and his cure is considered miraculous by all the mountain folk." I would add that the tablets were continued, as Dr. Milani expressed it, "in sufficient doses to keep the boy upon the human pathway."

On May 22nd, 1894, I was called to attend a tall, growing English schoolgirl fourteen years of age. I found her suffering from an acute attack of follicular tonsillitis, with great pain and difficulty in deglutition. This attack lasted until June 1st, happily without suppuration, and the patient made a satisfactory recovery. I observed with surprise and anxiety that while the temperature never rose above 103° F. the pulse varied between 140 and 160 until the febrile disturbance had subsided. From this time until June 12th the pulse varied between 100 and 120. It was then noted that the thyroid gland was moderately and symmetrically enlarged and the eyes rather prominent, but the upper lids could be voluntarily closed over the eyeballs in any position. There was no muscular tremor, but increased pulsation of the carotids was remarked. The diagnosis of Graves' disease presented no difficulty, and a course of galvanism to the cervical sympathetic was proposed in addition to other treatment, but the patient left Florence, and I did not see her again for some time. The mother, a lady noted for her cleverness and capacity in affairs, whom I saw frequently, gave me accounts of the case which I noted down at the time. The daughter grew much worse in England, and seems to have passed through a period of great danger, coincident with the first climacteric, which lasted two years. Under skilful treatment, including galvanism, however, she gradually recovered, and in January, 1890, it was noted that all the symptoms of Graves' disease had finally disappeared. From this time until December, 1891, the patient gradually drifted into a condition which a leading London authority then pronounced to be true myxœdema. In January, 1893, treatment with fresh thyroid gland was undertaken, which has been brilliantly successful in relieving the symptoms, and the patient, by continuing to take an appropriate quantity of the above preparation, has remained comparatively well.

In June, 1887, I attended another schoolgirl fifteen years of age, a short, rather thick-set Italian of the upper class. She had menstruated irregularly for about six months, and previously to this period had always been well and strong. The family history upon both sides was notably neurotic. The thyroid gland was more enlarged and the eyes more prominent than in the case just mentioned, but the pulse was less frequent (90 to 100) and the nervous excitability not nearly so great. A certain coarse muscular tremor of the extremities was noted, and the patient complained of being unable to close the eyes when lying down, so that they were often very dry in the morning. It was found that she could not completely close the upper lids over the eyeballs looking down except by pushing them with the fingers. In this case of Graves' disease it was decided to prescribe galvanism of the cervical sympathetic every other day. The patient was instructed to lead a quiet, restful life and to avoid all excesses. This treatment was continued, with short intermissions, until October, 1888, when menstruation had become regularly established, and recovery from all the symptoms of Graves' disease had occurred. From this time, with the exception of an attack of peripheral facial paralysis (right) due to a chill, from which she also recovered, the patient's general health was remarkably good until November, 1893, when various anomalous symptoms were first noticed, but chiefly of sluggish circulation, mental hebetude, and intolerance of cold. There is no doubt that the thyroid gland had also been growing smaller. No treatment was then undertaken, as the patient left Florence for the winter. She consulted me again in October, 1894, and decided to undertake systematic treatment. There had been no rapid change during the year's absence, but all the symptoms were a shade more accentuated. The temperature,

which had been normal in November, 1893, was now 97.4° F., the pulse had changed from 78 to 65, the skin was paler, drier, and less active, and the patient's whole appearance was indescribably different. If I may be allowed the comparison, she seemed to have merged her former personality into that of a more placid, apathetic, and slightly larger twin sister. As the patient could not be persuaded to continue the fresh sheep's thyroid gland, first prescribed, however prepared, the five-grain tablets already mentioned, of which a fresh supply had arrived, were prescribed. At first three tablets daily were given, cautiously increased to six, which dose it has not been necessary to increase. The effect was satisfactory from the very first, and the patient now (Dec. 10th, 1894) declares herself—and, indeed, appears in all respects—to be perfectly well. She is taking three tablets daily at present, and will remain under careful observation in future. I would add that either the fresh sheep's thyroid or the five-grain tablets have proved so satisfactory in every case thus far that I have not found it necessary to try later and perhaps more elegant preparations. Our present Italian Custom laws also render the importation of pharmaceutical novelties vexatious and difficult.

In June, 1892, a Swiss woman forty-four years of age consulted me. Her history, as noted down at the time, is as follows. She had married young and had borne several children, but the relation had proved a very unhappy one. Until 1888, however, she had enjoyed robust health. At that time she suffered from a great mental shock, succeeded by grievous family complications, which had continued to distress her ever since. In 1889 menstruation became irregular and after a twelvemonth finally ceased. Shortly after the shock mentioned she began to suffer from palpitation, breathlessness, swelling of the neck, prominence of the eyes, great nervousness, and insomnia. These symptoms continued for some months after the final menstruation (May, 1890), but gradually disappeared. She had never submitted to regular systematic treatment, but had taken medicine for hysteria from time to time. She had remarked that both before and after the climacteric all the symptoms were invariably aggravated for the first four or five days of the regular monthly time. Since then she had gradually lost control of her voice, which was sometimes fairly strong and clear, at other times muffled and indistinct, but always losing force. What chiefly distressed her, however, was inhibition of brain power and a sense of overpowering fatigue and melancholy. She slept fairly well, but was never refreshed thereby. There was lack of appetite, but digestion, although sluggish, was fairly good, and the bowels were always constipated. She suffered very much from the cold, and was invariably worse in cold weather. No organic lesions were discovered. The skin was pale, dry, and harsh; the hair was unusually thick, long, and lustrous, but latterly it had been falling out. She complained that the hands and feet were swollen at times, but this I did not observe. The tissue about the eyes was slightly swollen and the cheeks were pale. Her facial expression was notably anxious. The treatment prescribed consisted in attention to diet, regulation of the bowels, and the administration of hypophosphites of iron, strychnine, and quinine with arsenic. This treatment was continued, with intermissions, in Switzerland, where she spent the summer. She was distinctly better when I saw her again in the following November. During the winter, however, in spite of treatment, all her symptoms became aggravated, and in June, 1893, she was distinctly worse than the year before, when I first saw her. Her appearance did not suggest myxœdema, and I could not satisfy myself that atrophy of the thyroid was present, but it was decided to make a cautious trial of the same tablets of compressed dry thyroid gland powder. At first three were given daily, being then increased one at a time to six tablets daily. The effect was simply amazing, and after a few weeks the patient expressed herself, and, indeed, seemed to be, perfectly well. One or two tablets daily have been taken since, and she remains in good health.

Florence.

FOOTBALL CASUALTY.—During a recent match a Notts Forest left wing forward sustained an injury, which on medical examination was found to be a muscular adhesion in the vicinity of the sciatic nerve, and he will probably not recover the full use of one leg for some time.

AN OCCURRENCE OF MILK INFECTION.

BY JAMES NIVEN, M.A., M.B. CANTAB.,
MEDICAL OFFICER OF HEALTH, MANCHESTER.

ON Nov. 7th, 1894, Dr. Henry Ashby sent me a note in reference to a number of cases of illness which had occurred in Victoria-park, Manchester, some of them having come under his professional observation. The symptoms he described were diarrhoea, sickness, and abdominal pain. Those attacked were all supplied by one milk dealer, and he was of opinion that circumstances pointed to the milk as being the cause of the attacks. On that day and the following day I called at a few houses in Victoria-park, the addresses of which I had received from Dr. Ashby, and inquired into the circumstances under which their illnesses had occurred. All the families visited had received their milk from one dealer, and, so far as I was able subsequently to ascertain, all the families attacked in a similar manner at that time received the same supply, and other individuals not so supplied were found to have partaken of that milk. The chief points which I ascertained in the preliminary inquiry were that the attacks in the great majority of instances occurred on the night of Nov. 5th and in the early part of Nov. 6th. As a rule the persons attacked had partaken of unboiled milk. The milk supplied on the morning of Nov. 5th first produced the symptoms. It did not seem to make much difference in the result whether a small amount of milk in tea or coffee, or a large amount, was used. One woman was positive that all milk brought into the house was boiled, and in a number of instances the milk had been warmed. One occurrence of illness after the use of boiled milk is, however, scarcely sufficient to found a conclusion upon, as an oversight might have been made. Thus, at the first house I went to I was told that the children attacked always had their milk boiled, except on that particular morning. In the second house four persons escaped. One had had boiled milk, two others never used it, and the fourth only took a little in tea. The three attacked had had unboiled milk. In a third house ten were attacked and three escaped. Two of these did not have milk at all. Those attacked all took milk freely. At a fourth house a girl who came to clean the steps received a glass of milk, and was subsequently ill with the same symptoms as those attacked in the household. At another house, not in Victoria-park, five members of the family were taken ill—one on the night of Nov. 4th, one on the night of the 5th, and three others on the 7th. This household was the only one in the street supplied by the milk dealer whose milk was concerned. A considerable time elapsed—at least eight or nine hours—between taking the incriminated milk and the occurrence of symptoms of illness.

The conclusion drawn from these preliminary visits was that the phenomenon was probably one of bacterial growth in the body—i.e., of infection—from the use of this particular milk-supply. On Nov. 8th I obtained a sample of the milk supplied on Monday evening from a patient of Dr. Ashby, and took it to Professor Delépine, who very kindly undertook to make plate cultivations from it and otherwise to examine it bacteriologically. This milk had an unpleasant odour. Another sample of the milk supplied on Wednesday, Nov. 7th, which I obtained on a visit to Victoria-park on Nov. 8th, also had a disagreeable odour, which I seemed to recognise at the time but could not locate. On subsequently learning what had happened at the farm I seemed to recollect the odour as resembling that of "sweet pus." On Nov. 8th I also saw Dr. Waddell, of Rusholme, who had visited a large number of cases. On the previous day he called at the farmhouse from which the incriminated milk came, but beyond general insanitary conditions he ascertained nothing, and he was assured that there was nothing the matter with any of the cows. He informed me that the farmer had two supplies, one from his farm and another from Derbyshire, and that those attacked in Victoria-park had received their milk only from the farm, this special supply being retained for their use. Those who were supplied with the Derbyshire milk had escaped.

On Nov. 9th I called at the farm along with Mr. King, the veterinary surgeon of the Corporation. Mr. King made a careful examination of the cows, and found nothing in their condition which suggested that any of them could have

produced milk so toxic as that sent out from this farm. I asked the farmer a good many questions, interrogating him closely about the health of the cows and the health of the milkers, and of those who had to do with the milk otherwise. He informed us that a milkman had recently left him. We discovered nothing in reference to either man or cow. I also inspected the farm premises along with Mr. Martin, medical officer of health for Gorton, in whose district the farm is, and his Inspector. Close to the farmhouse is a tip of midden-privy refuse belonging to the Gorton Local Board, which Mr. Martin informed us might contain 40,000 tons of material of that kind. The farm is bordered on two sides by streams which meet below, one coming from this tip, and very foul, the other comparatively clear, but also contaminated with sewage and with matter from a tripe-boiling place. The water used to wash the pails was tepid. Mr. Martin took the temperature of this water, which was 92° F. A3 was subsequently ascertained by Inspector Lord, the water used in cleansing the milk pails was kept in a foul cistern. The cows also drank from a pool in the yard which received drainage from the cowshed midden. The storage of the milk overnight was such as to expose it to warmth and contamination from the cowshed. It is needless to multiply particulars. The conditions were thoroughly insanitary and were such as to lend point to the bacteriological report of Professor Delépine on Nov. 12th, which is as follows:—

The Owens College, Manchester, Nov. 12th, 1894.
REPORT ON A SAMPLE OF MILK RECEIVED FROM DR. NIVEN ON
NOVEMBER 8TH.

The milk was coagulated, the coagula being pure white and opaque. The smell was sour, and reaction strongly acid. Microscopical examination revealed fat globules in part confluent; there was no cell visible, and no extraneous matter, with the exception of micro-organisms distributed uniformly through and between the coagula. These bacteria were mostly short, plump bacilli, and large coils of variable size, here and there forming chains (streptococci). Abundant growth was obtained in milk and bouillon, both aerobically and anaerobically at the temperature of the body, the growth being accompanied by the production of gases having a very offensive smell. Abundant growths are also obtained on agar at 37° C., and on gelatine at 21° C. By plate cultivations various organisms were separated, two of which were more abundant than the others. These were a streptococcus with large segment, and a microbe having the characters of the bacillus coli communis. (These organisms are under investigation.) A virulent form of the bacillus coli communis has been found associated with severe gastro-enteritis. It is probable that, by accident, some contaminated water found its way into some of the vessels used for collecting or distributing the milk. Two tame young rats and two guinea-pigs were given large doses of the milk (varying in amount from one-tenth to half of the weight of the animal) without any unpleasant effect. The animals showed no dislike to it, and in one case a second dose was taken as readily as the first. It is therefore evident that the illness produced by the milk was not the result of a simple poisoning.

SHERIDAN DELÉPINE.

Nevertheless, there seemed something unexplained, and in any case it was desirable to ascertain more about the extent of the mischief done. I had already, on Nov. 7th, sent an inspector to the farm for a list of the customers supplied with milk from the cows on the farm. He brought me back a few names of people who had not been ill. On visiting the farm on Nov. 9th I insisted on having a complete list of the customers—those supplied in the morning being discriminated from those supplied in the evening. Such a list was subsequently sent, but I may say that I put no great value on any statements made with regard to the exact allocation of the milks respectively from the farm and from the supplemental supply in Derbyshire. In any case no distinction in the number of attacks is observed between those said to have been supplied respectively in the morning and in the evening. So far as it goes this would seem to exclude the fouling of one particular pail or of one particular supply as the cause of the disease. The list of customers was divided on Nov. 12th among the respective district inspectors, who made an inquiry into the occurrences in the different families on the list. It was possible from the same list to ascertain approximately the names of the medical men who attended the families attacked, and a letter was sent requesting them to be kind enough to give a brief account of their cases. The account thus obtained has not been completed, but showed conclusively, if further proof were necessary, the dependence of the illness on a particular milk-supply. It is intended to publish the accounts given by different medical men, of course without names and addresses. On Nov. 15th Inspector Lord found the milkman who had left the farm, who informed him that a cow had been removed about Nov. 2nd. He also visited the farm in Derbyshire from which the supplemental milk-supply came, and on Nov. 17th he proceeded to trace the cow which had

been removed. On Nov. 19th the farmer came and stated that on Nov. 8th his attention was called to a cow with "gargil"—i.e., inflamed udder—the milk of which had been at that time, and was also on Nov. 7th, mixed with the milk of the other twelve cows on the farm. This cow was removed from the farm on Nov. 8th, and on Nov. 10th was slaughtered and sold for food.

"Gargil" or "garget," I am informed, is an acute inflammation of the udder, which often leads to extensive sloughing. In an article in the *Medical News* for Aug. 8th, 1891, Dr. Tower, of Milwaukee, gives a drawing of the microscopic appearances of a sample of milk from such an udder, showing streptococci and collections of micrococci. I am not aware of any similar outbreaks which have been ascribed to a case of gargil.

Altogether, 160 cases of illness have come to my knowledge in forty-seven families, but none of them were fatal. In forty-nine families amongst those given in the list of consumers no illness was experienced. It is probable, however, that many of these had not partaken of the milk. The total yield of the cows was given to me by the farmer on Nov. 9th as seven gallons at one milking—i.e., 112 pints in the day. Now a number of the households were very large and this would not have sufficed for them. Moreover, at the same visit I was assured that the families in Victoria-park were exclusively supplied with milk from the farm. These nearly all suffered from the use of the milk, and therefore I consider it likely that a number of the other families had other milk.

In endeavouring to form a judgment as to what was the element in the milk producing the mischief one had to consider the nature of the occurrence. The great majority of the illnesses began on the night of Nov. 5th and early on Nov. 6th. Evidently something new was imported into the situation. It is true that there was plenty of material round the farm to cause disease, and the abundant presence of bacterium coli commune in the sample examined by Professor Delépine was quite in accord with the conditions to which the milk had been subjected on the farm. But, then, it had been for years subjected to similar conditions, and nothing had taken place. Moreover, with so many members of the family suffering from diarrhoea it is possible that some contamination might have occurred in the house where the milk was obtained. The teats of the cows were far from clean at my visit, and the bacterium coli commune might have entered in that way, or it might have been introduced by contaminated water, and, as I have mentioned, the water with which the pails were washed could not be regarded as other than contaminated. But it is felt that there was something altogether new, and probably arising from something fresh imported into the situation, and that this something was probably disease in man or cow. Hence our persistence of inquiry. As it turned out, one out of thirteen cows was acutely ill, and the period of its acutest illness covered the period of the outbreak. The farmer says that he became aware of the illness of the cow on Nov. 6th, and it may be assumed that it had begun to be ill a day or two before then. It does not go for much, but he himself felt it necessary to remove the cow. The weight of probability is, I think, otherwise, greatly in favour of this cow having been the origin of the outbreak. We have thought it advisable to investigate this subject further. Mr. King has undertaken to get some udders from cows suffering from "gargil," and Professor Delépine has undertaken to investigate the bacteriology and pathology of milk from them. A detailed account of a number of the cases has been sent me by the medical men in attendance. It shows the time of attack, and, when ascertained, how much milk was used. Taken along with Professor Delépine's report it appears to point to bacterial growth as against the action of toxins. I have not been able to find an account of any outbreak similar to the above, although it seems likely that such must have taken place. An interesting account is, however, given by Professor Gaffky¹ of an illness characterised by rigor, diarrhoea, and fever (up to 105°-8° F.), with very severe general symptoms, and followed by prolonged convalescence, occurring on the same day in the assistant, chemist, and servant at the Institute at Giessen, in consequence of partaking of milk. The source of the infection was found in a cow suffering from hæmorrhagic enteritis. The same bacilli, short, very motile, and pathogenic for mice and guinea-pigs, were found in the dejecta of the cow and of the patients.

¹ Deutsche Medicinische Wochenschrift, vol. xviii., No. 14, 1892; see also Schmidt's Jahrbuch.

They were, however, absent from the milk. It is inferred that the milk of the cow must have become contaminated with dejecta. A matter of some consequence in the Manchester outbreak is the strong belief entertained at one household affected that the milk used had always been boiled. In other families this seemed to have prevented the illness. But there is no doubt whatever that the bacteria concerned in the outbreak were capable of resisting tolerably high temperatures, since, in some instances, the milk, the use of which had been followed by attacks, was warmed, and in other cases mixed with hot tea or coffee. Professor Flügge² discusses the effect of heat on the sterilisation of milk. He finds that the anaerobic bacteria which are to be found in almost every milk do in part resist boiling for a period of an hour and a half. "Of much more consequence, however, are the peptonising bacteria, which are frequently present in enormous quantities, grow best at a high temperature, possess a dangerous tenacity of life, not altering the milk perceptibly for a considerable time, though gradually imparting to it a bitter taste. Amongst the twelve species encountered were three which were found on several occasions in the ordinary milk of commerce, and which appear to have a special importance, inasmuch as their pure culture in milk evoked severe toxic effects in different experimental animals, and in young dogs especially produced violent diarrhoea, often leading to death. The spores of these peptonising bacteria stand heating in water or steam up to 100° C. for two, and in part even up to six, hours; the ordinary heating up to 100° for about three-quarters of an hour does not destroy them." Professor Flügge concludes that the ordinary process of sterilising milk by boiling is insufficient. In spite of that, a very large proportion of the infectious germs present in milk will be destroyed by boiling, sufficient to prevent many of them from reproducing disease. But it would certainly seem that we cannot afford to neglect other precautions in the conservation of milk, even if we do have it boiled before use.

In the course of this inquiry several questions of general moment have risen. If we are to assume that the infection in this case was due to disease in the cow, yet how far was this disease ascribable to the insanitary conditions to which the cows were subjected? In order to elucidate this question I inquired into the previous history of cows on the farm, and was informed that there had been no disease among the cows for seven years. Seven years ago nine cows were said to have died one after another of a disease characterised by rapid onset, weakness, and staggering. The exact nature of this disease, apparently, no attempt was made to clear up. Several of the cows at our visit had a temperature of 101° F. and one had a temperature of 102°. In regard to this one Mr. King was inclined to think that it was tuberculous. I can scarcely believe that animals placed under such conditions as existed on this farm would escape disease for seven years.

Then, again, how far are such conditions limited to individual farms and how far are they general? From my previous experience of dairy farms in a neighbouring district I should say that they are far below any standard of sanitation which should be tolerated; and from what I have heard of the keeping of cows in and around Manchester the whole trade must require investigation and amendment. But it would scarcely be possible to establish a high standard in one district and allow surrounding districts to retain their old conditions. To obtain the maximum of advantage from an improvement in the method of dairy farming this must be made general. For that purpose I would venture to suggest that a uniform code should be applied to all cowsheds, both in and outside our large towns, and that this should not be too stringent in regard to the size of existing cowsheds. Also that veterinary surgeons, at an adequate salary, should be appointed to districts to make periodical examinations of the farm premises and of the stock. They would be required at once to report any insanitary conditions on the farms, or any disease in the cows, to the sanitary authority in whose district the farm or cowshed lay, so that adequate measures of prevention might at once be taken. I cannot help thinking that many such occurrences as the above must take place, though on a more limited scale, and that a large amount of bad health, especially in infants, must be produced by an impure milk supply. It is the more necessary to exert ourselves in

improving the state of the farms and the conditions of milk storage, if, as Flügge's results indicate, boiling affords an insufficient protection against impurities in milk. The directions in which amendment are most urgently called for are these:—

1. The removal from the milk-supply of all milk from diseased cows, or from cows in an abnormal condition, and the prompt removal from the cowshed of diseased cows.
2. The supply of pure drinking water to the cows.
3. Cleanliness about the farm. The teats and udders of the cows should be carefully cleaned before milking, and milked with washed hands. They are, as a rule, merely stripped, often with dirty hands.
4. Adequate space, lighting, and ventilation should be provided.
5. The milk pails and vessels should be scalded after each milk round and carefully cleansed.
6. The milk should be stored on the farm in a dry, well ventilated, and clean place.
7. When retailed in shops it should be protected from dust.
8. It should be sterilised before distribution if possible.

ABDOMINAL SECTION DURING PREGNANCY.

By JAMES MURPHY, M.D. DURH.,
SURGEON TO THE SUNDERLAND INFIRMARY.

DURING the year 1893 I had occasion to perform abdominal section on four patients who were pregnant. Their histories, briefly, were as follows.

CASE 1.—The patient, a lady aged twenty-two years, the mother of one child aged eighteen months, was sent by Dr. Norie. She was quite well up to two days before my seeing her, when she was suddenly taken with intense abdominal pain and tenderness, severe prostration, and constant vomiting. She had not menstruated for three months and believed herself to be pregnant. On vaginal examination the uterus was found to be enlarged and pushed forwards by a hard mass in Douglas's pouch. It looked very like a case of extra-uterine gestation after rupture, but there was no hæmorrhage from the uterus, and extra-uterine gestation is very rare with patients who have recently been pregnant. She was at once (Feb. 10th) removed to the Sunderland Infirmary and her abdomen opened immediately after her arrival, when she was found to be three months pregnant. The tumour in Douglas's pouch was a parovarian cyst, being quite black owing to a twisted pedicle. The tumour was removed and the abdomen washed out and closed. The case was perfectly aseptic throughout, and the patient was attended in her confinement on Sept. 4th by Mr. Stobo of Southwick, who informs me that she had an easy labour and gave birth to a boy. Both mother and child did well.

CASE 2.—A young lady thirty-two years of age was sent into the Sunderland Nursing Institute under my care by Dr. Beveridge of Hendon, to have an ovarian tumour removed, she being about six months pregnant. The operation was performed on April 20th, at 12 noon. The tumour proved to be a solid round-celled sarcoma weighing about two pounds, with somewhat numerous adhesions. The labour pains commenced twenty-four hours after the operation; they were slight for the first few hours, but towards 10 P.M. they became very much worse, and the patient soon gave birth to a boy, who lived for about twelve hours. The convalescence was uneventful, and the patient left the institute in three weeks, her highest temperature being 99.5° F.

CASE 3.—The patient, a woman twenty-two years of age, was sent to the Sunderland Infirmary by Dr. Houseman of Houghton-le-Spring. She was two months pregnant, and on the left side of her uterus there was apparently an adherent ovary in which she felt considerable pain. I did not consider there was any occasion to open the abdomen until Oct. 23rd, when to my surprise she became very collapsed, and fluid appeared in the abdomen. I at once put her under chloroform, and on cutting down to the peritoneum discovered that this fluid was blood. Opening the peritoneum by a small incision I removed about twenty ounces of blood and washed out the abdomen with boracic acid lotion. The uterus was enlarged, both tubes and ovaries were healthy, and from the

² In an article in the *Zeitschrift für Hygiene und Infectious-Krankheiten*, vol. xvii., No. 2, p. 272, 1894, quoted in Schmidt's *Jahrbuch*.

right ovary there was a bleeding point from a small adhesion, which had apparently held the ovary down to Douglas's pouch until the growing uterus had stretched it, and it then got torn some hours before the operation. I secured this adhesion with a ligature, and, there being no further bleeding point, the abdomen was closed. She made an uninterrupted good recovery, and her pregnancy continued till the ninth month, when it was terminated by Dr. Houseman owing to accidental hæmorrhage. The child was born alive.

CASE 4.—On Aug. 29th Dr. Limont of Newcastle asked me to see with him a lady twenty-seven years of age, two months pregnant for the first time, who was suffering intense pain from a small ovarian tumour on her right side. I removed the tumour (about the size of a hen's egg), and the patient made an excellent recovery. At the end of a month she went for a fortnight to Bournemouth, where she unfortunately contracted a very severe attack of bronchitis, after which she suffered from albuminuria with considerable œdema of the legs, and on Feb. 15th she gave birth to a dead child. Since then the albumen has disappeared, and she is now quite well.

The above cases, being recent ones, are recorded to show that abdominal section can be safely done during pregnancy, a question which has been a good deal discussed in this country and in Germany during the past year. My own experience in a large number of cases of abdominal surgery and general surgery, such as amputations, removal of breasts, &c., is that it is very unusual for an operation to terminate pregnancy.

Sunderland.

NOTE ON THE TREATMENT OF DIPHTHERIA.

By G. HUNTER MACKENZIE, M.D. EDIN.,

SURGEON FOR DISEASES OF THE THROAT AND NOSE TO THE EYE, EAR, AND THROAT INFIRMARY, EDINBURGH.

THE marked success which apparently follows the treatment of diphtheria by antitoxin raises the question whether the action of this remedy can be expedited or assisted by any auxiliary treatment, and, if so, what are the means which can so assist? In cases in which the disease has extended to the larynx, with consequent more or less obstruction to the respiration, it appears to be essential to recovery that some mechanical means should be adopted to maintain the integrity of the respiratory passage until the antitoxin has had time, possibly by repeated injections, to act. Roux¹ affirms that under the influence of antitoxin the false membrane ceases to grow within twenty-four hours from the first injection, and detaches itself in from thirty-six to forty-eight hours, at the latest by the third day. The thesis I now wish to maintain is that in intubation or tubage the medical man has a safe, easy, and effective means of combating the conditions attendant upon impeded respiration, which the new system of treatment occasionally requires. In fifteen cases of intubation in diphtheria reported in detail by me² the average length of time during which the tube lay in the larynx was twenty-six hours, and several of the patients who died succumbed to other causes than respiratory impediment. If the patient can be tided over twenty-four hours by means of an operation which does not require the administration of an anæsthetic and is not accompanied or followed by hæmorrhage or shock, and if antitoxin be simultaneously administered, the remedy is allowed time to commence to act under the most favourable conditions. If, on the other hand, marked obstruction of the larynx has developed before the commencement of administration of the antitoxin, and if no special means be adopted to combat it, the patient may die, and, judging from some reports of cases which have appeared in the medical press, has died before he could be thoroughly brought under the influence of the remedy. From a fairly extensive experience of both tracheotomy and intubation in diphtheria I feel warranted in agreeing with Roux in the following expression of opinion. He says in the article previously referred to: "How many children may be spared tracheotomy if the serum were administered sooner? We can even say that with the use of serum

tracheotomy should, in the great majority of cases, be replaced by tubage. It is now no longer a question of leaving a tube in the larynx for days; it will suffice more frequently to retain it during twenty-four or forty-eight hours to prevent imminent asphyxia, and to gain time until the false membranes detach themselves. *Tubage is the complement of the serum treatment of the future*, tracheotomy will be the exception, and greatly to the benefit of the children." (The italics are mine.) But even if a longer period than from twenty-four to forty-eight hours be necessary to allow the therapeutic effect of the antitoxin to develop it can be afforded by intubation, as the following cases show.

CASE 1.—On April 19th, 1894, I was asked by Dr. Thynne of Edinburgh to meet him in consultation in the case of a boy aged six years, the subject of diphtheria. Membrane had been seen on the tonsils and adjoining parts of the pharynx, and had subsequently extended to the larynx. We found him *in extremis*, and as the boy's father positively refused to permit of tracheotomy being performed, it was suggested that intubation might be tried. This was accordingly done. The auxiliary treatment consisted in the administration of small hourly doses of mercury, and of a mixture of strophanthus and strychnine, with free alcoholic stimulation. The tube was permanently withdrawn on the fifteenth day. The patient recovered after a tedious convalescence.

CASE 2.—On June 15th, 1894, I was called by Dr. Hamilton Wylie of Pirrig to see a girl aged seven years, reported to be suffering from diphtheria, with great difficulty in breathing. Intubation was performed. The auxiliary treatment was on similar lines to that of Case 1. The tube was withdrawn on the tenth day. The patient recovered, with post diphtheritic manifestations during convalescence.

I may observe that I have never witnessed a patient in a worse plight than the child was in Case 1 before the performance of intubation. What struck the attendant physicians and myself in regard to the results of intubation in these cases were: (1) the great and instantaneous relief which followed insertion, and in Case 1 re-insertion, of the tube; (2) the easy manner in which it was borne by the little patients, and the absence of annoyance to them from its use; (3) no difficulty in swallowing whilst the tube was *in situ* in the larynx; and (4) the tube in each instance could easily have been retained for a longer period if such had been considered necessary. There seem to be good grounds for believing that intubation or tubage is a valuable auxiliary in the antitoxin treatment of diphtheria, and that the day is fast approaching when it will supersede tracheotomy—"greatly," as Roux observes, "to the benefit of the children."

Edinburgh.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A FATAL CASE OF ANOREXIA NERVOSA.

By C. F. MARSHALL, M.D. VICT., F.R.C.S. ENG.,

LATE SURGICAL REGISTRAR AND ANÆSTHETIST TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, W.C.

IN connexion with fatal cases of anorexia nervosa, an interesting example of which appeared in THE LANCET of Jan. 5th, 1895, it may be of interest to record another case of this affection which was under my care in 1890. The history is briefly as follows:—

A girl, said to be eleven years of age, but who looked nearly fourteen years old, was admitted to the North Eastern Children's Hospital on May 10th, 1890. The history was only of one week's loss of flesh, anorexia, and vomiting. Four years previously she was said to have had similar attacks. On examination she was found to be extremely emaciated, but there were no signs of organic disease. She had a wild, hysterical appearance, was very restless, and refused all food; her bodily strength, however, was greater than would be supposed from her extreme emaciation. (The abdomen was so sunken that the vertebral column and sacrum could be easily felt.) As she refused all food she was fed on enemata of peptonised milk, beef tea, and brandy. In

¹ THE LANCET, Sept. 22nd, 1894.

² Edin. Med. Jour., Jan.-May, 1892.

two or three days peptonised milk and beef tea were taken by the mouth in small and frequent doses. In ten days she could take a moderate diet by the mouth, but suffered from diarrhoea. On the thirteenth day after admission she rapidly became worse, the temperature rose to 102° F., and on the fifteenth day she died. At the necropsy some old caseous foci were found at the base of the left lung; the stomach was congested with scattered ecchymoses; the other organs were normal. The case was diagnosed as probably one of anorexia nervosa, but in spite of the great emaciation no fatal issue was apprehended till two days before death. This diagnosis was, in the absence of any lesion to account for death and in the absence of diabetes, supported by the post-mortem examination. The presence of the old tuberculous foci in the lungs is of interest, in that this disease was supposed to originate from latent tuberculosis; but in the above case the tubercle was too small in extent and too localized to have been a factor in the cause of death, which was presumably due to the inanition having proceeded too far for recovery before systematic and regular treatment was begun. Dr. Laségue, writing on this disease in 1873,¹ states that death in such cases is never due primarily to the anorexia, but to some secondary disease such as tubercle occurring while the patient is in a lowered condition. Sir William Gull,² on the other hand, records a fatal case with no organic changes except thrombosis of the femoral veins.

London, W.C.

OBLITERATIVE ARTERITIS IN A BOY FOURTEEN YEARS OF AGE.

BY BERTRAM W. BOND, M.B., B.S. DURH., M.R.C.S.,
L.R.C.P. LOND., L.S.A.

WHILE acting as locum tenens to Dr. Easby of Peterborough a boy fourteen years of age came to me suffering from a sharp attack of "shingles" extending round the left side of the chest and back. He was evidently in bad health, and on taking his left wrist to feel his pulse I discovered that none could be felt. No pulse could be felt anywhere in the left upper extremity until the subclavian was reached. Here the beat was synchronous with that of the right subclavian, but much feebler. The radial and brachial arteries could be felt as cord-like bodies. On questioning the boy he said that beyond occasionally having "pins and needles" in the left arm and fingers he had felt no inconvenience whatever, and in fact he was unaware of the condition. He usually suffered from chilblains during the winter months, especially on the feet. The collateral circulation was evidently good, for beyond a slight blueness of the fingers there was no other visible sign of deficient nutrition. The temperature of the fingers was practically the same on both sides, and there was no anaesthesia. As regards cause, there was no sign of cervical rib or other pressure on vessels, the heart sounds were normal, and no specific or rheumatic history could be obtained. There were no signs of congenital syphilis elsewhere. The pulse in the right radial was normal, and no undue thickening of arterial walls could be felt. The interest of the case lies in the early age of the patient. I have seen a similar condition at the age of twenty-three and twenty-four years, but believe it to be rarely seen in a patient as young as fourteen years.

Englefield Green.

CASE OF POISONING BY NUTMEGS.

BY T. G. SIMPSON, L.R.C.P. EDIN.

HAVING been in practice a great number of years without seeing, or even hearing, of a similar case, I think the following particulars of a case I had recently under my care may possibly interest some of the readers of THE LANCET.

On Sunday morning, Dec. 9th, 1894, during my absence, my assistant, Mr. E. Gibbs Smith, was called to see a woman twenty-six years of age. His report was as follows:—"I found the patient lying upon the bed in a drowsy condition and very delirious, the delirium taking the form of confusion and mistaking one person for another. There were fairly lucid intervals. She complained of a sensation of great tightness across the chest, of vertigo and faintness upon

attempting to stand. She had vomited several times, but unfortunately I was unable to see the vomited matter. The pulse was 75 per minute and rather feeble, as was also the heart's action. The pupils were normal. Inquiries of a person in the house elucidated the fact that the patient, a strong, healthy woman, had, being a week over her menstrual period, taken two nutmegs, bruised, in a small quantity of gin. I ordered her to be kept in bed and to be given a little strong coffee with a dessert-spoonful of brandy in it every half-hour. I also prescribed the following mixture every four hours: bromide of potassium, carbonate of ammonia, bicarbonate of soda, spirit of cajuput, and chloroform water." I saw the patient myself in the afternoon, and found her condition considerably improved, but still showing the symptoms described. I continued the same treatment, and the next day she was very much better, but still had some vertigo and was very weak. I discontinued the coffee and brandy, but kept on with the medicine, and by the following day she was able to get up, though still weak. The case has gone on favourably since. I may add that the nutmegs had no effect whatever in producing miscarriage.

OF

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

SLOUGHING OF URETHRA FROM PRESSURE BY A METALLIC RING; PLASTIC OPERATION; RECOVERY; REMARKS.

(Under the care of Mr. EDMUND OWEN.)

THIS case is an example of an injury by no means rare in children, usually in consequence of some act of their own in tying or twisting a ligature of some kind round the penis. A case, however, has been recently recorded in which the constriction was produced in an infant by a human hair, there being no evidence as to the manner in which it had been applied. The injury resulting does not often extend so far as it did in this patient, for, as Mr. Owen remarks, there is a probability that a traumatic stricture will yet develop, although the urinary fistula is closed by operation. Urinary fistulae in the penile portion of the urethra are difficult to close, and none of the recognised methods of operation introduced by Ricord, Nélaton, or Le Gros Clark were available here. Mr. Owen therefore performed a novel operation, as described below, with a successful result. For the notes of the case we are indebted to Mr. C. F. Marshall, surgical registrar.

On March 30th, 1894, a boy nearly twelve years of age was admitted to the Hospital for Sick Children for incontinence of urine. The boy's mother said that she first noticed a swelling of the penis about a month previously and applied fomentations to it. Latterly the boy had lost control over his urine. She knew nothing more. The prepuce and glans penis were greatly swollen. Behind the swelling there was a constriction caused by a metallic ring five-eighths of an inch in diameter. The ring, which originally surrounded the penis, had now ulcerated through for a considerable distance so as almost to amputate the organ, and there was a large urethral fistula at the seat of constriction, the result of an extensive sloughing. Chloroform was at once administered and the ring was cut through with bone forceps and removed. At the same time a large portion of the œdematous prepuce was taken away, and a catheter was passed down to the fistula, but it could not be got into the bladder. On May 2nd the œdema of the penis had gone down considerably, but there was still a great deal of swelling in front of the constriction. All urine was passed by the fistula. Ether having been administered, Mr. Owen cut down on the strictured part of the urethra and passed a grooved staff into the bladder; he then cut down upon the staff in the perineum and introduced a permanent drainage-tube into the bladder through the middle line. On June 13th, under ether, Mr. Owen dissected away all scar

¹ Archives Générales de Médecine.
² Journal of the Clinical Society, vol. vii., 1873.

tissue and a certain amount of skin from around the fistula, and having raised an oblong flap of skin on the pubes (leaving it attached at both ends) drew up the penis beneath it and stitched the edges of the flap to the margins of the skin around the fistula. He then made vertical cuts near the ends of the flap so as to take off the tension of the flap, which, to a slight extent, occurred when the penis had been slipped beneath the bridge. On the 20th the flap appeared to have united by primary union. On the 27th the boy was examined under chloroform. There was a minute opening at both the upper and lower edge of the flap, through which urine oozed; these spots were touched with solid nitrate of silver. The perineal tube was still kept in. On July 4th, under the influence of chloroform, the ends of the flap were cut free, and the perineal tube was removed. A week later there remained one minute fistulous spot at the upper margin of the flap; it was freshened up and sutured by Mr. Owen. On the 27th similar treatment was adopted. On Sept. 1st the fistula was entirely healed; most of the urine passed by the natural way, but there was a considerable stricture, a No. 6 English bougie being passed with difficulty. On the 25th the patient was discharged. The perineal opening had now quite healed. A No. 7 catheter was passed. He has been going on quite happily, but on Nov. 18th he was readmitted for examination of the urethral canal. The passage admitted a No. 6 catheter, which was passed every alternate day and kept in for about a couple of hours.

Remarks by Mr. OWEN.—From time to time aid is sought on behalf of a boy who has slipped his penis through a metal ring or who has tightly surrounded its root with a string or a horsehair, which is playing the part of the coat of Nessus. The venous and the lymphatic return being thus delayed, the penis and prepuce swell to a great size, and the removal of the metal band by the way in which it was put on is impossible. In some cases, as in that above reported, the ring can be cut with pliers and so removed. On one occasion a boy was brought to me whose swollen penis was encircled by a thick brass ferrule. This could not have been cut or filed off without risk of injury to the parts. Its removal was, however, easily effected by winding a thread around and pricking the swollen tissue to empty it of the œdema. The application of the thread was done as evenly as if one were "whipping" a splice in a fishing rod. When a piece of string or a horsehair has been tied round the penis it quickly embeds itself in the ulceration which its pressure causes, and so it disappears from view, and at the same time the œdematous skin on the distal side bulges over and hides the wound. In every case, therefore, of œdema of the penis in a boy, most careful search should be made, not only for a circumferential linear ulcer, but also for some inconspicuous mechanical obstruction to the return circulation. In the subject of these clinical remarks the brass ring was entirely removed from view; the mother knew nothing of it. The ring must have slowly been embedding itself, but as to when it gave rise to obstruction of micturition, or when to ulceration or sloughing of the urethra, there was nothing to show. Suffice it to say that when I first saw the boy the spongy part of the urethra had lost its floor to a very serious extent. Evidently it was of no use doing anything with him then, that part of the penis being girt with a deep ulcer and the tissues beyond it being swollen with an almost solid œdema. We contented ourselves, therefore, with keeping the penis bandaged and raised, all the urine escaping by the wound. When the swelling had a good deal subsided we established the perineal drain; and soon afterwards we denuded the under aspect of the penis and carried out the plastic operation. The urethra is now perfectly water-tight, but I am afraid that the unfortunate boy will have trouble at the seat of inevitable traumatic narrowing; such trouble, however, will not be due to the bridge of new skin, for it remains soft and full, but to the inevitable contraction of the new material which was developed from the granulation tissue at the seat of injury.

BURTON-ON-TRENT INFIRMARY.

A CASE OF ABDOMINAL SECTION FOR SARCOMA OF OVARY,
AND ONE FOR RUPTURE OF EXTRA-UTERINE
PREGNATION; REMARKS.

(Under the care of Mr. PHILIP MASON.)

SARCOMA of the ovary is a comparatively rare disease, is apt to show itself in early life rather than at a later age, and usually runs its course quickly, whether an operation be

performed or not. In these circumstances it has been questioned whether it is worth while to perform abdominal section and remove the diseased part. Freund¹ advises on this subject that, as we are unable to diagnose with certainty the presence of malignant disease before operation even in cases of extensive metastasis, an incision, with clearing of the peritoneum, is justified, and might produce a better general state of health; he considers that secondary tumours in the ante- or intra-uterine space should not contra-indicate operation. Schröder² found sarcomata in 10 out of 600 ovarian growths; and Olshausen noticed them 21 times in 293 cases. Amongst the cases of solid ovarian tumour collected by Leopold³ there were 12 of sarcoma, in 7 of which the tumour was on both sides; all those reported by Olshausen were similarly placed. It has been suggested by Anger⁴ that extra-uterine pregnancy should be regarded and treated as a malignant growth. There is no doubt that the life of the patient is in constant danger, the greatest danger being that of hæmorrhage, and the woman is fortunate who is so placed as to permit of abdominal section, as in the following case, otherwise a fatal ending must be expected. Schauta⁵ analyses 626 cases of ectopic gestation, the collective mortality of which exceeded 41 per cent. In a spontaneous course it reached a mortality of 68.8 per cent. The most common form is that of tubal pregnancy. For the notes of these cases we are indebted to the house surgeon, Mr. Charles Thompson.

CASE 1. Sarcoma of ovary.—A single woman aged twenty-one years was admitted into the Burton-on-Trent Infirmary on Oct. 2nd, 1893, complaining of pain and tenderness in the abdomen, with some swelling, obstinate sickness and diarrhoea, and a profuse irregular menstrual discharge of some weeks' standing. On examination the abdomen was found to be somewhat prominent, especially to the right of the median line, about an inch and a half below the umbilicus, where a distinct tumour could be felt, pyriform in shape, and about the size of a foetal head at full term. The tumour, which appeared to be fixed centrally, inclined somewhat to the right side and had two or three bosses on its surface, each about the size of a horse chestnut, the one on the right being more prominent, tender, and more inclined to point. A catheter could not be passed. On vaginal examination a hard mass was felt in Douglas's pouch, the uterus was not movable, and was displaced forwards; a sound passed two inches and a half. After being under observation with little change for about a month the patient became rapidly worse, the temperature rising in the evening to 104° F. and rarely falling below 101° during the day; there was considerable peritonitis, the tumour commenced to soften, and fluctuation was distinct over the spot which had been the most prominent and most tender. On Nov. 7th she was placed under an anæsthetic and a median incision made about four inches long. On opening the peritoneal cavity a large tumour was seen which appeared to spring from the right broad ligament, to which it was united by a pedicle and did not involve the uterus. In consistence it was partly hard and partly composed of cysts, one of which contained pus and appeared to be on the point of breaking, and ruptured during manipulation. The whole mass was removed with the right ovary and broad ligament, the cavity washed out, a drainage-tube inserted, and the wound stitched up. On the evening following the operation the temperature was 105.2°, the patient was very restless, and she complained of abdominal pain on deep inspiration. The temperature on the following morning fell to 99°. The greater part of the wound healed by first intention, but a small deep sinus remained when the tube was removed, and did not heal for about a month. During this time the patient gained weight rapidly and appeared to be doing well until Dec. 1st, when sickness and diarrhoea returned, with mucus in the stools. The temperature rose to 103°, and she sank into a typhoid condition. In four or five days she rallied, and on the 5th the temperature again fell to subnormal and remained so until the 13th, when she was allowed to sit up. After a day or two there was some return of pain, but no tumour could be felt. Thrombosis of deep veins appeared in the left leg on the 15th, and she complained of a deal of pain in the left knee, which subsided in about a fortnight. There was no further rise of temperature after the

23rd, and the patient was discharged on Jan. 4th, 1894, apparently well. About a week after her discharge she was attended outside the infirmary, and complained of pain and tenderness in the left iliac region; a small growth was there felt, which grew with such rapidity that it almost filled the abdominal cavity within a month. Distinct lobulated masses could be felt, and the peritoneal pain was intense. She died from exhaustion on Feb. 10th.

CASE 2. Extra-uterine foetation.—A woman aged twenty-eight years was admitted into the Burton-on-Trent Infirmary on June 13th, 1894, in a state of collapse. There was a history of three months' irregular menstruation with pain and swelling in the left ovarian region; the patient had become suddenly collapsed a few hours before admission. On opening the abdomen the left Fallopian tube was found to be distended by a tumour which had ruptured into the peritoneal cavity and was bleeding freely; there was a large amount of blood in the abdomen. The left ovary and tube were removed, the peritoneal cavity washed out, and the incision in the abdominal wall closed. The patient made a good recovery.

Remarks by Mr. MASON.—The tumour removed in Case 1 was sarcomatous in structure, and contained not only several fair-sized cysts, but also an unmistakable abscess with rugged walls. This was evidently on the point of bursting when the operation was performed. This is the second occasion on which I have found a similar condition to exist, my other patient being an elderly woman with a large tumour which, on removal, was found to be solid except for two large abscesses at some distance apart. In this case the tumour was universally adherent and had no pedicle, the abdominal-wall wound healed by first intention, but the patient became suddenly ill at the end of a fortnight and died from the effects of fecal extravasation, probably due to the injury of the bowel during the separation of the adhesions.

ROYAL VICTORIA HOSPITAL, NETLEY.

BONY ANKYLOSIS OF HIP-JOINT; MALPOSITION; OSTEOTOMY; RECOVERY WITH USEFUL LIMB; REMARKS.

(Under the care of Surgeon-Major H. R. WHITEHEAD, Assistant Professor, Military Surgery.)

THE operation described as the subcutaneous section of the femur below the trochanters was first performed by Mr. Gant in December, 1872, and we published an account of the operation in THE LANCET of the 21st of that month. There is little doubt that it is the operation which is best adapted for the correction of bony ankylosis of the femur in a bad position after disease of the hip-joint of a tuberculous nature. The principles of the operation described below were the same as guide the surgeon in Gant's operation; but there are one or two details which differ. For instance, Gant writes that the knife was "passed down to and over the femur, so as to make a transverse line across the bone; then the knife is withdrawn and, still keeping the thumb in position not to lose the track of the narrow subcutaneous incision, a thin, narrow-bladed saw is entered at the same point and passed along the track of the wound across the femur, which is then readily sawn through." Macewen's osteotome is such a useful implement that many surgeons now prefer it to the saw.

A trumpeter in the Royal Artillery, eighteen years of age, was invalided home from Egypt, and was admitted to the Royal Victoria Hospital, Netley, in November, 1893, suffering from hip-joint disease of nine months' duration. He enlisted at the age of fourteen years, and had enjoyed good health till March, 1893, when he began to feel acute pain in the right hip-joint, which was much increased by any movement or by pressure on the sole of the foot, and he was unable to walk. There was no history of a fall or any injury to account for the origin of the disease. He was admitted into hospital at Cairo. An abscess formed and pointed anteriorly; this was opened, and discharged for some months, ultimately healing in February, 1894. For some months he suffered from a hectic temperature. Extension was applied to the leg in June, 1893, which diminished the "starting pain" in the joint. On his admission to the Royal Victoria Hospital, Netley, in November, 1893, the patient was in a very feeble and emaciated condition. He had bedsores on his back, and a sinus existed in the right groin, discharging a purulent fluid; the track,

however, did not lead down to dead bone. The right thigh was flexed on the abdomen, the knee was semiflexed, the foot was everted, and the leg and thigh rotated outwards. Lordosis was present even when no attempt was made to straighten the limb, and this condition was greatly exaggerated on any attempt being made to do so. As soon as the bedsores had healed sufficiently extension was applied, but failed to bring the limb into a better position. There was hardly any pain about the hip, and the discharge lessened daily, till in February the sinus had completely healed. No movement could be obtained in the hip-joint. In April, as all pain had ceased and the sinus had completely healed, the efforts to improve the position of the leg by extension having also failed, it was decided to place the patient under the influence of an anæsthetic, to decide definitely the nature of the ankylosis, and if possible to straighten the limb. After complete anæsthesia had been produced it was found that absolutely no movement could be procured in the hip-joint. The knee, which was semiflexed, was, however, straightened. The next day the hip-joint was entirely free from pain, and no doubt now existed that the ankylosis was of a true bony nature. It was, therefore, decided to divide the femur in its upper part, with the view of giving the patient a straight and useful limb. On May 1st, after the limb had been carefully prepared by washing and the skin rendered aseptic, the patient was placed under the influence of chloroform. He was then placed on his left side and the right thigh laid on and supported by a large sand pillow. An incision was made in the line of the shaft of the femur, commencing three inches below the tip of the great trochanter, about an inch and a half long, and carried down to the bone. The periosteum was divided and the soft parts were held aside by retractors. A Macewen's osteotome was introduced and the shaft of the femur was divided just below the small trochanter, as suggested by Gant. On attempting to straighten the limb some bands of fascia on the anterior aspect of the limb, attached to the anterior superior iliac spine, were found to be tense, and were divided subcutaneously by a tenotome; the limb could then be brought into a straight and good position. The operation wound was closed by two silver sutures and a continuous horsehair suture, and the part was dressed with an aseptic gauze dressing. An interrupted long splint was applied to the side, and extension by a 7-lb. weight was also employed. The patient made a complete recovery after the operation. His temperature did not rise above 99° 2' F.; it reached this on the evening of the day of operation and afterwards remained uninterruptedly normal. The wound was dressed on the sixth and twentieth days, and healed at once. Seven weeks after the operation the long splint and extension were removed; the leg and thigh were in excellent position, and complete consolidation of the shaft of the femur had taken place. On measurement the right leg was found to be a shade under half an inch shorter than the left. Excellent movement existed in the right knee-joint. A Thomas's hip-splint was applied for a few days and the patient allowed to get about. He gained strength rapidly, and at the end of nine weeks was able to walk with comfort with the aid of a stick and a slightly raised sole. The pelvis allowed of much motion. He was discharged from hospital on July 9th, ten weeks after the operation, and although unfit for military service he had a very useful leg and was quite capable of earning his living in civil life.

Remarks by Surgeon-Major WHITEHEAD.—In this case the choice of operation seemed the only difficulty. Adams' operation for division of the neck of the bone did not seem applicable in this case, as suppuration had evidently taken place in the joint, and probably absorption of the neck of the bone had taken place to some extent. Barton's method of dividing the bone by a chain saw was thought of, but in experiments on the bones of animals the saw invariably jammed and became useless. Macewen's osteotome seems in every respect a very suitable and satisfactory instrument. Some little trouble was caused in getting the metal to the right temper to avoid chipping of the edge, and as a matter of fact a piece of the edge did chip off at the operation; it was left in the bone, but it produced no discomfort.

ROYAL INSTITUTION.—The Friday evening meetings of the members commenced on Jan 18th, when a lecture was delivered by Professor Dewar on Phosphorescence and Photographic Action at the Temperature of Boiling Liquid Air.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Cycling and Heart Disease.

AN ordinary meeting of this society was held on Jan. 14th, the President, Sir WILLIAM DALBY, being in the chair.

Sir BENJAMIN WARD RICHARDSON read a paper on *Cycling and Heart Disease*. He commenced by saying that a few months ago Dr. Petit of Paris had read a paper before the French Academy of Medicine bearing on disease and cycling,¹ in which several sudden deaths from heart disease during cycling were referred to, and the possible dangers attending cycling exercise were commented upon. Sir B. W. Richardson, who had been a practical cyclist since 1877 (over sixteen years), and who had ridden with numberless riders of different ages and sexes and under the most varied conditions, ventured, therefore, to detail from his experience certain of the effects he had observed. He divided his paper into the following heads: (1) the immediate effect of the exercise on the rider; (2) the after-effects, as observed in the consulting-room, and the conditions in regard to the heart and circulation under which riding was favourable or unfavourable; and (3) a summary of the more salient medical considerations. With regard to cycling and its effects upon the body at large, Sir B. W. Richardson said that the exercise told primarily and most distinctively on the heart, in which it differed from other exercises. In all riders at all ages it produced at once a quickened circulation, though riders themselves might not be conscious of the phenomenon. The effort might be so extreme as to cause the pulse to rise from 65 or 75 to 200 beats per minute, and although after a longer time it sovered down it was always a quickened action which continued so long as the rider was at work. This act of quickened movement accounted, the speaker observed, for the astounding journeys a fully trained cyclist could undertake, journeys lasting two or three days and nights when the cyclist was in his prime. The same probably accounted for his endurance as against sleep, the circulation through the brain being one continued series of waves by which the molecular change of the brain occurring during natural sleep was suspended. The sounds of the heart and the readings of the pulse were then described, and the conditions under which the heart increased in action, and sometimes underwent enlargement. He had, however, never once seen a rider embarrassed by cardiac overstrain, faintness, breathlessness, angina, or vertigo so as to be obliged to dismount. Indeed, he had known a practical rider who could climb a hill on his machine, but could not mount a flight of stairs on his feet without breathlessness and slight palpitation; also he had never seen a sudden death from cycling. Under thesecond head Sir B. W. Richardson remarked that he had met with instances in which after some years of cycling there was evidence of cardiac disease, with general languor and inability to sustain fatigue if exercise were again tried on the machine. On the other hand, he had known examples in which even an octogenarian had kept up the exercise in a moderate degree, apparently with benefit to the circulation, and who in one journey had ridden from London to Bedford. In certain instances he had seen what appeared to be benefit arising from cycling, even when there was an indication of some disease affecting the circulation. He had known good arise from it in cases of varicose veins, in examples of fatty degenerations, and unquestionably in conditions of anæmia. After discussing opposite conditions, in which excessive cycling had become a definite cause of injury to the circulation, he passed to his third head in the following summary. "First, cycling, when carried on with moderation, may, in so far as the healthy heart is concerned, be permitted or even recommended by practitioners of the healing art. Secondly, in all cases of heart disease it is not necessary to exclude cycling. It may even be useful in certain instances where the action of the heart is feeble and where signs of fatty degeneration are found, since increased muscular exercise often improves the condition of muscle, and of no muscle

more than the heart itself. Thirdly, as the action of cycling tells directly upon the motion of the heart the effect it produces on that organ is phenomenally and unexpectedly great in regard to the work it gets out of it. Fourthly, the ultimate action of severe cycling is to increase the size of the heart, to render it irritable and hyper-sensitive to motion, the cycling acting upon it like a stimulant. Fifthly, the over-development of the heart under the continued over-action and extreme over-action affects in turn the arterial resilience, modifies the natural blood pressure, and favours degenerative structural change in the organs of the body generally. Sixthly, a fact that has only been incidentally noticed in this paper is worthy of notice—namely, that in persons of timid and nervous natures ('neurotics') the fear incidental to cycling, especially in crowded thoroughfares, is often creative of disturbance and palpitation of the heart, and ought to be taken account of as a piece of preventive advice. Seventhly, in advising patients on the subject of cycling it is often more important to consider the peripheral condition of the circulation than the central. Enfeebled or worn-out arteries may be more dangerous than the feeble heart, and, when connected with a heart that is over-active, are seats of danger. This same remark would, of course, apply to cases where there is local arterial injury, as in aneurysm. Eighthly, venous enlargement seems rather to be benefited than injured by cycling, and conditions marked by sluggish circulation through veins are often greatly relieved by the exercise. Ninthly, there are three things which are most injurious in cycling—(a) straining to climb hills and to meet head winds; (b) excessive fatigue; and (c) the process of exciting the heart and wearing it out sooner by alcoholic stimulants, and the omission of light, frequently repeated, and judiciously selected foods. Lastly, the time has arrived when practitioners of medicine everywhere should make observations for themselves that confirm or confute these observations and add to them so much more that I of necessity have omitted."

The PRESIDENT, in thanking Sir B. W. Richardson for his paper, referred to the influence which remarks from him exerted on the public mind, and rejoiced that from him should come words of reassurance and caution in the use of the cycle. It was apparent that cycling exerted nothing like the strain upon the heart which was entailed by other forms of athletic exercise, such as rowing or sparring.

Dr. SANSON congratulated Sir B. W. Richardson on having made a substantial addition to our knowledge on a subject of growing importance. A practitioner, he thought, should be something of a cyclist to be able to appreciate and advise upon the disturbances incidental to riding. He deprecated the absurd resolutions of the French Academy of Medicine with regard to the dangers of cycling, and regarded the recommendation to adopt searching anthropomorphic measurements in those intending to ride as bordering upon the ridiculous. Referring to his oration on Rapid Heart, delivered before the society, he could only recall one instance in a cyclist, and he had met with no instance of irregular heart among riders. He thought the worst form of exertion was the running to catch a train, which produced both irregularity and rapidity of heart beat. The influence of cycling was decidedly more in the direction of good than in that of evil. As a therapeutic agent in the treatment of actually existing heart disease it was quite in accord with the recommendations of Professor Hirtl of Munich, who prescribed physical exercise, but he thought cycling had many advantages over climbing, which Professor Hirtl extolled. He looked upon the cycle as an important hygienic and therapeutic agent, and thought it was responsible indirectly for the immense moral improvement noticeable in the track and the era of the cycle.

Dr. MACFAGH said it was a very important point in cycling to avoid pushing against one's inclination up steep gradients. He felt the exertion much less than that of other forms of athletic exercise, and found that under it he maintained a perfectly even body weight. The chief strain, he thought, fell upon the nervous system, and was liable at first to induce sleeplessness; this, however, soon wore off.

Dr. ROUTH inquired as to Sir B. W. Richardson's experience of ladies cycling.

Dr. WASHINGTON ISAAC referred to Mr. Bridgman of Berkley developing heart disease while he was a cyclist and to his making the discovery himself with a binaural stethoscope.

Dr. FLETCHER LITTLE said that the tremulousness so often complained of formerly had diminished greatly since the improvement in saddles and tyres. He thought there was

¹ THE LANCET, Sept. 15th, 1894.

no better treatment for mitral disease and dilated heart than the cycle, which was quite in accord with the system adopted by Schott of Neuenheim. The danger and anxiety of riding through crowded thoroughfares should be avoided, especially by nervous persons and those suffering from heart disease, who should also eschew hills. The exercise and facility for inhaling fresh air were of immense importance to both men and women, especially those following sedentary occupations.

Dr. BLACK mentioned a patient with gout who had been recommended the cycle, and asked if it could be looked upon as a remedy for gouty heart.

Mr. SOLOMON SMITH thought the tendency of geared wheels was to bring back the exertion of cycling to that of climbing. He considered the best feature in this form of exercise was the predominance of motion over exertion, especially in the treatment of cardiac disease, and should recommend the avoidance of geared wheels.

Sir B. W. RICHARDSON, in reply, said Mr. Bridgman was not oppressed with any fear of riding after he found he had cardiac disease, but continued his exercise. He was not prepared yet to say how actual disease of the circulation might best be cured by the use of the cycle. He recognised the occurrence of sleeplessness and sometimes twitching as of the effect of vibration after riding, but he could not agree that the principal effect was on the nervous system. The rise of the pulse from 75 to 200 beats indicated that the circulation was first affected. He did not pretend to prescribe the fall and exact measure of utility of the cycle in therapeutics, he came rather as one who had collected a few flowers by the way and offered them for consideration and arrangement by his audience.

PATHOLOGICAL SOCIETY OF LONDON.

Enlarged Spleen.—Five Brains from Insane Patients.—Serous Pachymeningitis in a Syphilitic Child.—Cancer of Mamma.

An ordinary meeting of this society was held on Jan. 15th, Dr. PAVY, the President, being in the chair.

Dr. COLLIER exhibited the Spleen of a female child aged six. Enlargement was first noticed at the age of two, and gradually and steadily increased up to the time of death. The mesenteric glands were also enlarged. No change in the blood was observed. On removal the spleen weighed 4lb. 2oz., the total body weight being 23lb., so that it represented more than one-sixth of the total body weight. A sister aged four had died four years previously with enlarged spleen. On microscopic examination the splenic reticulum was seen to be replaced by very large endothelioid cells, in places packed closely together, and filling the whole splenic sinuses. In these places the blood-supply was almost nil, and the large cells showed a tendency to degenerate. In these places, also, there was a slight increase in the thickness of the trabeculae. The Malpighian corpuscles could not be distinguished. Small arterioles were seen closely surrounded by the large cells. In some of the retro-peritoneal glands examined the adenoid tissue was seen to be largely replaced, especially at the periphery, by large cells similar to those in the spleen. Some small grey points like tubercles occurred on the small omentum, and were found to be young lymphoid glands.—Mr. WALTER SPENCER suggested the possibility of tubercle or syphilis having some influence in the production of the enlargement, and proposed that the specimen be submitted to the Morbid Growths Committee.—Dr. ROLLESTON, who seconded this proposition, added that either lymphadenoma or leukaemia might account for it.—Dr. WALTER CARR said the case much resembled those occurring in infancy associated with simple anaemia and rickets. Haemorrhage only occurred in extreme conditions of the sort. He thought either syphilis or rickets was probably the cause.—Dr. HERRINGHAM thought it was difficult to make a genuine disease of splenic anaemia. The term did not explain much.—Dr. COLLIER, in reply, said the signs of rickets were very slight, and no mention was made of them in the post-mortem report, there was no evidence of syphilis, and the anaemia was not intense.

Mr. C. F. BEADLES exhibited Five Brains from patients who had died insane. The first showed the right lobe of the

cerebellum ploughed up by an extensive haemorrhage which had made an opening into the subdural space. The vessels were atheromatous and the brain softer than natural. The patient was a man sixty-five years of age who had been insane four years, suffering from delusions and great depression. The second exhibited a large collection of fluid occupying the site of the right lobe of the cerebellum, which was much shrunken. The basal arteries were diseased and the right internal carotid occluded by a calcareous mass at its entrance to the cranium. There was also atrophy of some of the cerebral convolutions, with dilatation of the ventricles. The patient was a woman aged fifty-six who had suffered four months from wild excitement and delusions of persecution, with epileptiform convulsions and left hemiplegia. The third, from a female aged eighty-two, showed enormous dilatation of the ventricles, with disappearance of the central grey ganglia. It was removed from a patient who had been imbecile and dumb from birth, and more actively insane for thirty-four years. The fourth showed great deficiency of brain substance in the left cerebral hemisphere, the central part being occupied by a large collection of fluid. There were also dilatation of the ventricles and signs of old haemorrhage; it was from a female aged seventy-seven, with insanity of thirty-one years' duration, maniacal and violent. The fifth exhibited great atrophy of the left cerebral hemisphere and of the right side of the cerebellum, and was from an insane patient aged sixty-six who had been demented and epileptic fourteen years.

Dr. WALTER CARR showed a specimen of Serous Pachymeningitis with Atrophy of some of the Cerebral Convolutions. The patient was a child aged nineteen months who had suffered from a severe form of congenital syphilis, for which she first came under treatment at the Children's Hospital, Chelsea, when seven weeks old. She was the first living child after four miscarriages, suffered almost constantly from nasal discharge, and only a few weeks before death had slight epiphysitis at the lower end of each femur. The birth was easy and natural, and no history of any head injury could be obtained. General convulsive attacks were frequent from two weeks old, but there was no permanent rigidity. The mother stated that at the time of death the child was like an infant of three months, never sitting up alone, and taking very little notice. Death occurred rather suddenly from a low form of pneumonia. At the necropsy the head was not enlarged and the fontanelle was nearly closed. The dura mater was lined on its inner side by a thin membrane, thickest over the vertex, and having a peculiar gelatinous appearance and consistence on its inner aspect. There was a good deal of thick gelatinous material over the convolutions and at the base of the brain, with slight excess of rather sticky fluid. Microscopically there was no evidence of recent haemorrhage. The brain only weighed eighteen ounces, and presented large, not quite symmetrical, areas of marked pallor, depression, and hardening round each posterior limb of the fissure of Sylvius. The thoracic and abdominal organs except the lungs were healthy. The case seemed to correspond to the very rare condition described by Dr. Gowers as serous pachymeningitis. Reference was made to a somewhat similar case described by Dr. Wheaton, in which, however, there were sixteen ounces of fluid under the dura mater and the hemispheres were uniformly shrunken; also to a general sclerosis of the external surface of the brain in a syphilitic child aged twenty months, recorded by Ashby and Wright. It was concluded that the meningitis was probably syphilitic, and had led to the cerebral atrophy and sclerosis. The case also illustrated one way in which congenital syphilis may cause idiocy.

Dr. HERBERT SNOW exhibited slides of two cases of Mammary Cancer, which at one end presented the phenomena of so-called "Columnar Epithelioma" or "Duct Cancer," and at the other the Acini typical of Scirrhus Carcinoma. He contended that both the above terms embodied an erroneous principle, and that no classification of epithelial morbid growths could be based on morphological attributes *per se*. The shape of an epithelial cell was an extremely variable and inconstant quality—that of the bladder, for example, changing with its relative distension. How readily columnar cells passed on slight modifications of the environment into squamous, or *vice versa*, had been amply proved by Bland Sutton, Shattock, Haycraft and Carlier, Roedel, &c. The columnar shape was a common attribute of cells coating vegetations within cysts or cyst-like cavities with fluid contents, such as the bladder, ovary, and thyroid gland. The rarity of the so-called "columnar epithelioma" in the larynx showed that

columnar cells when malignant developed a lesion indistinguishable from that of squamous. "Duct cancers" of the mamma were intra-cystic carcinomatous vegetations; the cysts were much more often dilated acini than dilated ducts; the cells from which they sprung were those of the gland parenchyma, therefore identical with the parent cells of scirrhus; and any clinical differences, such as tardiness in infecting the glands, were due to the cyst wall, which constituted a rigid envelope or "capsule."—Mr. JACKSON CLARKE said that there was good clinical ground for separating such cases from cancer; it was well to retain the distinguishing term "duct cancer."—Mr. C. F. BEADLES mentioned one case in which the condition of duct cancer was combined with well-marked scirrhus of the gland.—Dr. KANTHACK said that cancer beginning in epithelial structures retained the character of the epithelium. With regard to the apparent exception of squamous cancer commencing in the larynx he stated that the lining membrane was mostly transformed into squamous epithelium soon after or during childhood, affording a good example of metaplasia. Columnar carcinoma occurring in the larynx usually arose from the lining membrane of the ventricle, which retained its columnar character throughout life. In the rectum the epithelium of surface and ducts was alike columnar, as it was in the ducts of the breast, all carcinomata in these regions being columnar unless penetrating from the skin surface. He thought the specimens exhibited were not conclusive.—Mr. BOWLEY said there might be a superficial resemblance between the two, but no real identity. He would limit the term "duct cancer" to a columnar growth having a villous arrangement, and the specimens exhibited did not correspond to this. The clinical course and naked-eye appearances were very different in the two growths. He had collected thirteen cases of "duct cancer" of the breast, the first fifteen years ago, and they were all living at the present time.—Mr. SHATTOCK adhered to the principle that squamous epithelium gave rise only to squamous-celled carcinoma, never columnar. He thought Mr. Bowley was too exclusive in his limitation of "duct cancer." It rested with Dr. SNOW to prove his contention. Referring to Mr. Beadles' case of associated "duct cancer" and scirrhus, he alluded to the evidence of metaplasia in extruded polypus of the uterus, where the columnar epithelium assumed the squamous type, and he drew attention to the fact that during development there were no fixed varieties of epithelium, pointing out that the transitional phase might continue later.—Mr. BOWLEY explained that he recognised two forms of cancer in ducts, one the villous kind, of which he had been speaking, the other a columnar form, which might be identical with scirrhus.—Dr. SNOW, in reply, said some words in pathological language were used in quite different senses, and he thought it would be a very useful step to institute a representative committee to revise the nomenclature of morbid growths. He drew attention to the variation in shape of the bladder epithelium in different states of distension of that organ.

At the conclusion of the meeting the PRESIDENT announced that on Feb. 5th Dr. Washbourn would open a discussion on Pneumococci, especially in connexion with Immunity.

CLINICAL SOCIETY OF LONDON.

Abdominal Section for Unusual Conditions.—Acute Intestinal Obstruction from Gall-stone.—Loculated Empyema.—The Antitoxin Committee.

AN ordinary meeting of this society was held on Jan. 11th, the President, Mr. J. W. HULKE, F.R.S., being in the chair.

Mr. A. W. MAYO ROBSON read accounts of Three Cases of Abdominal Section for Unusual Conditions: (1) Tuberculous Disease of the Liver; (2) Complete Volvulus and Strangulation of the Great Omentum; and (3) Traumatic Hæmorrhage without External Wound. He pointed out that his cases resembled one another only in the treatment and its results, but he hoped the cases might prove of interest individually. The first case related was one of tuberculous abscess of the liver which was treated by incision, rubbing in of

iodoform, and drainage. The patient, whose illness had extended over twelve months and who was reduced to an extreme degree of weakness, had completely recovered his health. Attention was drawn to the literature of the subject, and the case as well as the treatment adopted were shown to be extremely uncommon. The second case was one of volvulus and strangulation of the omentum following the reduction of a large inguinal hernia. Peritonitis led to the suspicion of reduction *en masse*. Abdominal section revealed the whole of the omentum in a state of deep congestion verging on gangrene, connected by two twisted cords with the stomach above and the left inguinal canal below. Recovery followed removal. So far as Mr. Robson knew the case was unique. The third case was one of traumatic intra-peritoneal hæmorrhage without external wound, in which the patient was in so serious a condition that exploration to reveal the actual site of the hæmorrhage would probably have led to death on the table, but where incision, washing out with hot saline solution, and drainage had been efficient in arresting the bleeding and bringing about recovery.—The PRESIDENT said that in his experience in the post-mortem room he had never met with a large solitary caseating tuberculous mass in the liver unaccompanied by tuberculous manifestations elsewhere, and he thought it impossible to positively exclude it in the present instance. He had also never seen or read of such rotation of the omentum as was present in the second case. There was scarcely any abdominal viscus except the liver in connexion with which the circumstance of rotation had not been observed. He cited the spleen, kidney, and uterus as instances. Mr. Sutton, at the Middlesex Hospital, last year removed a spleen which had such a long stalk that it reached the left inguinal region. The stalk was twisted on itself several times. In an instance recorded in Billroth's publication the uterus had been lifted out of the pelvis by a large fibroid, and had contracted adhesions to the ascending colon, its cervical part being lengthened and formed like a strand twisted several times, around which the Fallopian tubes were twined.—Mr. EVE asked on what evidence Mr. Robson described his first case as one of tuberculous abscess of the liver. In reference to the possibility of its being actinomycosis he observed that the absence of clubs did not prove the disease not to be actinomycosis.—Mr. MAYO ROBSON explained that tubercle bacilli were found in the abscess contents, and microscopical examination showed the absence of any appearances resembling the ray fungus.—Mr. MAKINS said he did not see how Mr. Robson excluded the possibility of tuberculosis of the peritoneum in the first case. With regard to the third it struck him that when the abdomen was opened and a ruptured viscus found the operation was often too long. When a rupture of the liver was found very little could be done for it.—Mr. CROFT mentioned that on one occasion he had removed a spleen in order to arrest hæmorrhage from that organ, the abdomen at the time being full of blood. The patient was in a very marked condition of collapse and was apparently on the point of dying. As it was, she lived for some hours. He thought it was a mistake to delay ascertaining the exact source of the hæmorrhage. If it proceeded from such an organ as the spleen the chances were small of the hæmorrhage spontaneously ceasing. In all such cases an exploratory operation should be performed at the earliest possible moment.—Mr. W. H. BATTLE said there did not appear to have been any signs of rupture of a viscus, and it was quite impossible to say where the hæmorrhage came from. Such cases were always very obscure. Only last autumn he had under his care at St. Thomas's Hospital a boy who fell on his face while playing at leap-frog, and was brought in with symptoms of intra-peritoneal hæmorrhage, manifested by intense shock. There was a dull area on the left side, extending as far as the left linea semilunaris. He had been and was then vomiting, but there was no rigidity of the abdominal muscles. The dullness in the abdomen gradually extended until it reached the right linea semilunaris. The boy ultimately recovered. He had no idea where the blood came from, but he thought it might be from a torn mesentery. He raised the question as to what symptoms are to be held to justify the performance of laparotomy forthwith: would tympanites, for example, be such a sign?—Mr. BENHAM asked whether any examination was made of the chest in Mr. Robson's first case. According to Louis's law the presence of tubercle anywhere in the body was always associated with tubercle in the lung.—Mr. MAYO ROBSON, in reply, said he did not think there could be any doubt as to the tuberculous nature of the disease in the first

case. The patient was ultimately discharged as cured, and there was no trace of disease anywhere. With regard to the second case, he thought it was very difficult to account for the rotation. If in his third case he had tried to find the source of the bleeding he felt sure he would have lost his patient; even flushing the abdomen was sometimes followed by shock.

Mr. FREDERICK EVE described a case of Acute Intestinal Obstruction from Gall-stone, with Laparotomy, Removal of Stone, and Recovery. A man forty-two years of age was admitted to the London Hospital on March 19th, 1894. Four days previously he had been attacked with pain in the abdomen, vomiting, and absolute constipation. The vomiting was continuous. Nothing was ascertained by palpation. He denied having had previous abdominal trouble. Belladonna was prescribed and a large enema given, after which he passed a small fluid motion and felt easier. The next morning he was worse and the abdomen more distended. On March 20th laparotomy was performed. When the abdominal muscles were relaxed under ether a hard body feeling like a rifle bullet could be felt in the right iliac fossa; this was evidently an impacted gall-stone. It was exposed and was found to occupy the ileum two or three inches from the ileo-cæcal valve. The small intestine above the obstruction was considerably distended. The large intestine was completely empty. The ileo-cæcal orifice was brought into view and an attempt made to push the calculus through it, but unsuccessfully. The calculus was then worked up the ileum into a free loop which could readily be brought outside the abdomen, and after applying elastic ligatures above and below it was extracted through a longitudinal incision. This was closed with Lembert sutures of fine silk, a graft of omentum was attached, and the intestine replaced in the abdomen. Rectal alimentation was maintained for four days. The further progress of the case was uneventful, and the patient left the hospital after being in it about four weeks. After the operation it was elicited that eighteen years previously the patient had been subject to severe attacks of pain in the epigastrium, sometimes accompanied with vomiting. For seven or eight years he was never entirely free from pain, but about once a week had a severe attack. Ultimately the pain and attacks of vomiting ceased quite suddenly. He had never passed a gall-stone. This trouble might be referred to the presence of a biliary calculus in the gall-bladder and the sudden cessation to its passage into the duodenum; so that it might be inferred that the calculus had occupied the intestine for some ten years—a circumstance not without precedent. The calculus was cylindrical in shape and its circumference was three inches and a quarter. Mr. EVE remarked that at first the result of laparotomy for this apparently simple form of obstruction was by no means encouraging. Writing in 1889, Dufourt collected nine cases, all of which proved fatal except one in which the stone was slipped into the large intestine. Mr. EVE had collected eighteen cases occurring subsequently to this period, of which (after incision and suture of the intestine) nine recovered. This advance might be attributed to improved surgical technique, for operative interference was not longer delayed in the earlier than the later group of cases. In conclusion, the following suggestions were made with regard to treatment:—1. When a diagnosis was possible expectant treatment should be tried, as one-third of the cases of marked obstruction from gall-stone recovered without operation. 2. But operative interference should not be long delayed, as the patients were nearly all aged, the mean age being sixty-four years. 3. After opening the abdomen the calculus should, if possible, be forced through the ileo-cæcal valve. 4. If the calculus be immovable or at a distance from the valve, and the intestine healthy, the stone should be excised. 5. When the intestine was inflamed, and the stone immovable and adherent to it, an attempt might be made to break the calculus up with needles. This failing, it should be extracted, the intestine fixed to the abdominal wall near the wound, and surrounded with iodoform gauze. 6. In only one case out of twenty-seven was it found necessary to resect the intestine on account of ulceration.—The PRESIDENT observed that all would probably agree with the conclusions formulated by Mr. EVE.—Mr. MAYO ROBSON fully concurred in the utter impossibility of making any diagnosis in cases of obstruction by gall-stone.—Mr. EVE replied.

Mr. J. W. BROWNE recounted a case of Empyema associated with Hydatids of the Liver.

NORTH-WEST LONDON CLINICAL SOCIETY.

Erythematous Ulceration of the Extremities.—*Hereditary Congenital Spastic Paralysis.*—*Nævi cured spontaneously and by Electrolysis.*—*Malformation of Chest.*—*Multiple Osteotomy for Deformity.*—*Exophthalmos.*—*Myelitis.*—*Hæmatoma of the Pinna.*—*Hallux Rigidus.*—*Polypus of the Frontal Sinus.*

A MEETING of this society was held on Jan. 9th, Mr. F. DURHAM being in the chair.

Mr. JACKSON CLARKE exhibited a boy suffering from Ulcers on the Hands and Legs, pain in the knee, and coldness of the extremities. Bazin's and Raynaud's diseases were discussed, and Mr. Clarke distinguished the present as an unusual form of erythema iris.

Dr. GUTHRIE showed two of three children in a family affected with Hereditary Congenital Spastic Paralysis. He also showed the father, who had exaggerated knee-jerks, ankle-clonus, and a spastic gait. The mother and two other children were healthy. This disease in early infancy was thought to be rare.—Dr. CAGNEY believed the disease to be more common in very young children than was supposed.—Dr. GILL spoke of similar cases under his care.

Mr. NATHAN showed the remains of a Congenital Nævus of the Scalp. There was left a patch of atrophic skin nearly bald. The case had been mistaken for ringworm. He also showed a Nævus of the Pinna which had been electrolysed.—Mr. CLARKE thought that the first case was unique and of exceptional interest.—The CHAIRMAN discussed the treatment of nævi.

Dr. HARRY CAMPBELL showed an extreme instance of Barrel Chest in a man with Emphysema, and pointed out the manner in which this deformity affected the circulation.

Mr. JACKSON CLARKE exhibited a girl in whom both the Femur and the Tibia had been submitted to Macewen's Osteotomy Process. The result was good, and as the muscles developed there would be a satisfactory cure.—Mr. BRODIE commented on the case.

Mr. GORDON BRODIE showed a boy with Exophthalmos. The cranial bones were enlarged and the chest misshapen. The upper part of the sternum projected backwards and pressed on the trachea. The child had adenoids.—Dr. CAMPBELL indicated the high palate and the facial expression, which clearly indicated nasal obstruction. He had no doubt the latter had influenced the development of the entire cranium.—Mr. JACKSON CLARKE believed that the shape of the head was due to mechanical causes in utero.—Mr. COALL thought that the efficacy of nasal obstruction in causing remote changes was overrated.—Dr. CAGNEY regarded the deformity both of the head and of the chest as typical of rickets, and he referred to the constant association of adenoids with that disease.

Dr. HARRY CAMPBELL showed a case of recovery from Myelitis, and he advocated the use of blisters in this and other acute spinal diseases.—Mr. COALL spoke also of the efficiency of blisters combined with ergot in acute spinal diseases.

Mr. JACKSON CLARKE showed a case of Hæmatoma of the Pinna. There was no associated psychosis. The tumour grew and pain increased. He, therefore, proposed to operate.—Mr. BRODIE and Mr. RIDLEY commented on the case.

Dr. ATKINSON (for Mr. MAYO COLLIER) showed a case of Hallux Rigidus and also one of Polypus of the Frontal Sinus.

CAMBRIDGE MEDICAL SOCIETY.

Fibroid Tumour of the Uterus removed per Vaginam.—*Gun-shot Wound.*—*Salicylates in Acute Rheumatism.*

A MEETING of this society was held on Dec. 7th, 1894, Mr. HYDE HILLS, President, being in the chair.

The PRESIDENT exhibited a specimen of a portion of a Large Fibroid Tumour which he had removed per vaginam with the écraseur. The notes of this case he had brought before the society on a previous occasion.

Mr. WHEBBY showed a young man who shot himself accidentally seven weeks previously. Holding a gun by the muzzle in the right hand, a charge of small shot entered the arm at the level of the axillary fold and shattered the humerus into many fragments, not injuring the artery or trunk nerves.

The bone fragments removed made up two inches and a half of the entire shaft of the humerus. These were extracted through the large aperture of entrance very slightly touched with a knife for convenience of delivery. The exit wound was made free for removal of shot. No splints or bandages were used for five weeks, but Stromeyer's cushion and shawl wrappings. When healthy granulation appeared the drainage-tube was removed and light splints applied, so that good bone union resulted. The slight congestion produced by the splints used at the later stage of treatment was probably useful in gaining union. Mr. Midelton of Harston, who brought him to the hospital, had so managed to treat the shock of this great injury that the patient was able to give answers to questions, especially as to skin sensitiveness in the injured limb. Mr. Wherry had reported a similar case many years ago in which Stromeyer's cushion was used; recovery ensued with a useful limb, but not with so little suppuration as in this case treated with modern methods of antiseptics and irrigations.

Dr. P. W. LATHAM read a paper on the Administration of Salicylates in Acute Rheumatism. He said: "We have now become so familiar with the successful treatment of acute rheumatism by means of salicylic acid and salicylates that it may seem somewhat superfluous for me to address you on the subject. But cases have come under my observation in which objections have been taken to the use of the remedies, on the ground either that they disagreed with the patient, producing nausea, vomiting, &c., or that notwithstanding fairly large doses of the drug the pains have not been relieved, the temperature has not been reduced, or most serious of all, cardiac or other complications have arisen during the time the patient was taking the remedy and when apparently he was under its influence. Now it is in preventing the development of these complications that, when properly administered, the remedy so strikingly shows its power, truly acting as a distinct specific. What are the conditions to ensure success? In 1885 I formulated the following seven rules:—First, the true salicylic acid obtained from the vegetable kingdom must alone be employed. Secondly, give the acid without any alkali or base. Thirdly, place the patient fully under the influence of the drug. Fourthly, give the patient from forty to eighty grains daily, for ten days, after all pain and pyrexia have passed away. Fifthly, let the patient's diet consist entirely of milk and farinaceous food for at least a week after the evening temperature has been normal. Sixthly, take care to maintain a daily and complete action of the bowels. Seventhly, let the patient be enveloped in a light blanket and with no more bedclothes than are sufficient to keep him from feeling cold. The object of the treatment now is to cool the patient—not, as in former times, to sweat the poison out of him; and the cooler he is kept the sooner will the temperature be lowered.¹ The causes of failure with this remedy, as far as I have been able to judge, are: (1) insufficient doses at the commencement, (2) the non-administration of purgatives such as calomel, and (3) feeding with substances other than milk, such as beef-tea, broths, &c., especially in the earlier stages. I have seen cases where the temperature had remained at from 100° to 102° F. for several days under the administration of moderately large doses and the remedy seemed ineffectual, but on giving five grains of calomel at night, repeating it if necessary the following night, and feeding the patient exclusively on milk, the disease has at once declined and run a favourable course. The administration of calomel (followed if necessary by purgatives) is the best adjuvant to the use of the salicylates. And here I am only calling to our aid a plan of treatment which half a century ago was found to be of signal service. Referring to the three modes of treatment—by venesection, by opium, and by purgatives—which were in vogue at the time, Dr. P. M. Latham says, with regard to the last: 'As this plan of treatment works prosperously day after day in its immediate effects, so day after day it gives an earnest of the remedial impression it is exercising upon the whole disease. It abates the fever, it softens the pulse, it reduces the swelling, and it lessens the pain. In short, it subdues the vascular system like a bleeding, and pacifies the nervous system like an opiate; and often in the course of a week the acute rheumatism is gone. In three days there is often a signal mitigation of all the symptoms; and in a week I have often seen patients who have been carried helpless into the hospital, and shrieking at the least jar or touch or

movement of their limbs, risen from their beds and walking about the ward quite free from pain.' Of this plan, often so striking in its operation and often so satisfactory in its results, I have some further remarks to make. It is called the purgative plan; yet its purpose is achieved by calomel and purgatives conjointly. The purgatives would not answer the end without the calomel; of that I am quite certain; neither would the calomel answer without the purgatives, unless it produced of itself ample evacuations from the bowels. It is probable, in short, that the remedial efficacy of the plan resides essentially in the calomel; in calomel, however, not as mercury, but as itself—calomel. If the specific effect of mercury—salivation—arise, it is not only beside our purpose, and against our wish, but it begets a serious hindrance to the use of calomel in sufficient quantity for the end in view. Thus the whole plan is frustrated. Having begun one plan of treatment we are obliged to take up with another. Time is lost, the case is perplexed, the disease is prolonged, and the patient perhaps injured. Now, if in the treatment of acute rheumatism you were to choose one indication and abide by it, and to trust one class of remedies, and to it only, you will find more cases that admit of a readier cure by the method now described than by either of the two former. You would find the aggregate of morbid actions and sufferings, which constitute the disease, more surely reached and counteracted and more quickly abolished by medicines operating upon the abdominal viscera only than by those which influence either the bloodvessels only or the nerves only. You would find in calomel and purgatives a better remedy than either venesection or in opium.² Again, there are cases in which the salicylates cause nausea or sickness; this is more marked if the salt of the artificial acid has been employed, but it does sometimes occur even after the use of the salt of the true acid. How is this to be avoided? A common form of administration is: sodii salicylatis, gr. xx; aq. cinnamomi, unciam; to which, if necessary, five grains of carbonate of ammonia may be added. Or it may be given in the effervescent form, as, sodii salicylatis, gr. xx; sodii bicarbonatis, gr. xx; syrupi aurantii, drachmam; aq. chloroformi, ad unciam cum semisse; cum acid citric, gr. xvii. Or instead of the citric acid give three drachms of lemon juice, replacing the syrup of orange by half a drachm of simple syrup. It must, however, be borne in mind that in some constitutions repeated doses of lemon juice may induce sudden prostration, as was observed many years ago when the remedy was employed in the treatment of rheumatism. Administered in any of these forms, however, the salicylate may give rise to some nausea, and a certain feeling of repugnance may be induced in the patient to the medicine. This may be avoided entirely by giving the salicylic acid itself, made up into pills, in the way I have previously mentioned. I have never seen the remedy in this form cause nausea unless it was in individuals who have a difficulty in swallowing pills. And there is good reason for it. Made up in this form the pills do not readily undergo solution in the stomach. The acid is insoluble in the acid juices there, and the pills pass on into the duodenum before solution takes place. In fact, when the bowels are acting very freely and the pills have been freely administered, I have occasionally seen them unchanged in the evacuations.³

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

Rupture of Intestine.—Uterine Fibroids.—Exhibition of Fibroids.—Abdominal Tumour.—Cirrhosis of Liver.—Cholecystotomy.—Trophic Changes following Nerve Irritation.—Thiersch's Method of Skin Grafting.—Tumour of Omentum.

A MEETING of this society was held on Jan. 10th, Mr. F. PAGE, President, being in the chair.

Mr. WILLIAMSON showed a man after operation for Rupture of Intestine. Just after dinner the man fell, striking the abdomen on a chair. Two hours later hæmatemesis occurred. The patient was admitted to hospital thirty hours after the

¹ Dr. P. M. Latham's Works. New Sydenham Society, vol. i., pp. 123-124.

² In acute rheumatism complicated with albuminuria the use of the drug is contraindicated. Dr. Noel Paton's experiments show "that this drug has really an irritating action on the kidneys." Journal of Anatomy and Physiology, January, 1886, p. 25.

accident. The abdomen was distended, the pulse 130, and there was still hæmatemesis. The intestines were found covered with firm lymph. At the junction of the duodenum and jejunum there was found a protrusion of mucous membrane about the size of the thumbnail. The wound was enfolded and sutured, and the abdomen washed out with a saline fluid. No drainage was employed. Recovery was interrupted.

Mr. WILLIAMSON also showed a patient after operation for Uterine Fibroids. She was forty-seven years of age, married, nulliparous, and had suffered from hæmorrhage for two years. The uterine and ovarian arteries were ligatured, the tumour excised, the opened cavity of the uterus disinfected by the thermo-cautery, and two flaps of uterine tissue and peritoneum made and sutured together. Two weeks after operation a fibroid the size of a walnut escaped by the vagina.

Mr. RUTHERFORD MORISON exhibited a series of Fibroids treated by different methods—viz., vaginal hysterectomy; extra peritoneal treatment of pedicle; intra-peritoneal treatment of pedicle—(a) leaving uterus and ovaries intact, (b) removing tubes, body of uterus, and tumour; and total hysterectomy.

Dr. HUME showed a patient aged fifty years with a Tumour of moderate size. There was no hæmorrhage, but very severe pain. There were extensive adhesions between the tumour, the bowel, and the omentum. On separating these both tubes were found distended with pus and were removed. The tumour was drawn forwards, surrounded by a permanent elastic ligature, and the stump treated extra-peritoneally. This he regarded as the safest though not the ideal method.—Mr. PAGE referred to two cases he had shown at the last meeting, the extra-peritoneal method being employed in one of the two.—Dr. G. MURRAY said fibroids in women approaching the menopause should not be operated on. Apostoli's treatment checked the hæmorrhage and might get the woman over the menopause.—Dr. HUME, in reply, said that he had had little success from Apostoli's treatment. He still believed in removal of the ovaries, and gave details of successful cases recently treated in this way.

Dr. D. DRUMMOND showed: 1. A patient who up to fifteen years ago was a heavy drinker. He had been left with a Cirrhotic Liver, which was practically cured. The liver and spleen were both very large and were adherent to the abdominal wall, so that the anastomotic circulation was established in the abdominal wall and the portal circulation relieved. 2. A man twenty-eight years of age, who was admitted to hospital in May last with a heart beating 200 per minute; he was nervous and breathless; the symptoms came on after a fright. There were no murmurs. He had now aortic and mitral insufficiency and pericardial thrill. There had been no rheumatism until Dec. 27th, 1894.

Dr. HUME also showed: (1) Woman after Cholecystotomy; the gall-bladder was distended and contained calculi, and a large one was removed from the cystic duct by incision. 2. A patient with Trophic Changes following Nerve Injury. In April the patient received an incised wound on the inner aspect of the upper arm, and in December was admitted with the tips of the three outer fingers gangrenous, and wasting of muscles of the forearm, thumb, and interossei. The median and ulnar nerves were found divided and were sutured.—Dr. A. E. MORISON had recently met with a case of injury to the external popliteal nerve caused by a blow on the head of the fibula. There was complete paralysis of all the muscles supplied by the torn nerve and sensation was also absent. He cut down on the nerve and found a clot of blood in the sheath, but no division of the nerve itself as was expected. In a short time recovery was complete.

Mr. RUTHERFORD MORISON showed two cases illustrating Thiersch's Method of Skin Grafting.

The PRESIDENT exhibited a Tumour of the Omentum removed from the abdomen of a man. It was the size of an adult head and consisted chiefly of clotted blood.

EDINBURGH OBSTETRICAL SOCIETY.

Pseudo-hysteria in Pregnancy.—Clinical Aspects of Utero-sacral Cellulitis.—Ante-natal Pathology and Heredity in the Hippocratic Writings.

A MEETING of this society was held on Jan. 9th, Dr. BARBOUR, President, being in the chair.

The PRESIDENT read notes on a case with symptoms of Pseudo-hysteria in Pregnancy, going on to apparent dementia. Death occurred shortly after labour. The child was born dead, with contractions. The patient, who was six months pregnant, became feverish and fretful, and showed different hysterical symptoms. She afterwards had fugitive rigidity of the limbs and ultimately contractions and paralysis; she was subject to flushings and the reflexes were increased. There was great difficulty in swallowing, and as the disease developed she passed urine and faeces involuntarily. Her face acquired an imbecile aspect, and her general appearance and condition were similar to that of dementia. It was decided to induce labour, but this occurred spontaneously. With each pain the patient had an epileptiform convulsion. After two hours and a half a more severe fit occurred, evidently causing the death of the child, as no foetal movements could be felt or the heart heard after its onset. As the patient's pulse failed the labour was completed with the application of the forceps. After delivery all paralysis disappeared, only a little contraction remaining. On the third day the temperature rose to 105° F. and the patient died. At the necropsy there was no evidence of syphilis found in any organ. The kidneys showed some small cortical abscesses. There was no other evident pathological condition found except in the brain. The pia arachnoid was thickened and opalescent over the hemispheres and vertex. The arteries had local thickenings of the walls, and a thrombus had formed in part of the basilar artery. Recent softening of the brain was found, affecting part of the convolute nucleus and extending to the base. The arteries showed endarteritis, and the capillaries had their nuclei multiplied. The whole condition was one similar to that usually found in dementia, the paralytic symptoms being due to commencing changes in the vessels. The foetus, which died during labour, showed contractions of all the limbs, with flexure of the fingers. It, strangely, had contractions affecting its limbs exactly similar to the mother. These persisted for eighteen hours after birth, and were evidently not due to rigor mortis.

Dr. WILLIAM FORDYCE read a paper on the Clinical Aspects of Utero-sacral Cellulitis, giving the results of cases where the disease was present as a pure disease without complication. It was found in nulliparæ and multiparæ, most frequently in the latter. The cause was found in septic infection from the endometrium or cervix, constipation, or fissure of anus. The symptoms usually complained of were pain in the back, sterility, dyspareunia, frequent micturition, pain on defecation, and dysmenorrhœa. He considered the form of dysmenorrhœa pathognomonic of pathological ante-flexion. The pain occurred during the flow and in inverse ratio to the amount of the flow. As the flow diminished the pain increased.—An interesting discussion followed, in which Professor Simpson, the President, Drs. Ballantyne and Haultain, and others took part.

Dr. J. W. BALLANTYNE read a paper on Ante-natal Pathology and Heredity in the Hippocratic Writings. These works were evidently the collected observations of different writers of the time of Hippocrates. They were well acquainted with the luxation of joints in infants and described fully the appearances of club-foot. Their view of heredity was based on the theory that the generative material was derived in certain proportions from the different humours of the body. Maternal impressions were noticed by them, and ante-natal diseases and injuries were described.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of this society was held on Wednesday, Jan. 9th, at 11, Chandos-street, Cavendish-square, Mr. Christopher Heath, vice-president, in the chair. Mr. Heath moved, from the chair, a resolution expressing sincere sympathy and condolence with the president, Sir J. Paget, on the bereavement he had sustained through the lamented death of Lady Paget. Two new members were elected, and the deaths of three reported. There were no fresh applications for assistance. A sum of £1193 10s. was voted for distribution among the fifty-three widows, nine orphans, and four orphans on the Copeland Fund. The expenses of the quarter amounted to £77 17s. 6d. The Christmas present (£303) had been given on Dec. 19th to the widows and orphans in receipt of grants, £5 to each widow, £2 to each orphan, and £5 to the orphans on the Copeland Fund.

Reviews and Notices of Books.

The Life of Richard Owen. By his Grandson, the Rev. RICHARD OWEN, M.A. Two Vols. London: John Murray. 1894.

THESE entertaining volumes depict the life of our great palæontologist mainly from its social and domestic side. Notwithstanding the engrossing nature of his scientific labours, he went much into society, played chess and the violoncello with some skill, ardently admired the drama, and was altogether a man who had many friends and some opponents as well. Prime Ministers, Church dignitaries, and peers figure largely in these pages, and there are more than occasional glimpses of exalted personages such as members of our own Royal Family, the Emperor of Brazil, the Queen of Holland, and some others. A very large number of the letters written and received by Owen have been preserved, and both he and his wife were indefatigable diarists. The wealth of material thus provided has been skilfully manipulated by the biographer so as to produce a smooth and almost continuous narrative, consisting in no small degree of the actual phraseology employed by the Owens and their correspondents. The interest of the story is maintained from first to last. There are no abstruse technical disquisitions likely to be tedious or unintelligible to the general reader, nor is there any trace of the learned polemics in which Owen was involved; but the scientific references and details with which the books abound are introduced incidentally, as it were, in the order of their occurrence and in the parts of the biography with which they are naturally connected. Owen's home life seems to have been singularly untroubled and happy. Deprived in infancy of his father, who was a West India merchant, he and his sisters were brought up in Lancaster by their mother, a woman evidently well fitted in every way for her charge, and constantly regarded with the warmest affection by her son. As soon as he presented himself at St. Bartholomew's Hospital in 1825, after quitting Edinburgh University, he had the good fortune to secure the patronage of Abernethy and to be made his prosector. In the following year he became a Member of the Royal College of Surgeons of England, and, through Abernethy's instrumentality, was appointed assistant to the conservator of the somewhat neglected museum which had been purchased by the Government from John Hunter's representatives and handed over to the Royal College of Surgeons. The connexion with the Hunterian Museum thus begun was continued for thirty years, being terminated only in 1856, on his appointment to be superintendent of the Natural History Departments of the British Museum. In 1830 he became a life member of the Zoological Society, and in the following year contributed to their proceedings eight papers on the anatomy of various animals. In 1830 he made the acquaintance of Baron Cuvier, in whose department of research he was destined to labour so successfully. Cuvier died in 1832; Owen was occupied solely with the Hunterian Museum Catalogue and with zootomy until 1837, when he produced his first palæontological paper, a Description of the Cranium of the *Trodon Platensis*, but he had already attracted the attention of scientific men by his Memoir on the Pearly Nautilus, published in 1832. In 1834 he was elected a Fellow of the Royal Society. In 1835 he married Caroline Clift, daughter of the Conservator of the Hunterian Museum; they had one son, who died in 1866, leaving a widow and family. In 1837 Owen was appointed to the newly-created office of Hunterian Professor to the Royal College of Surgeons. An incident which illustrated his sagacity, and moreover took an unusually firm hold of the public mind, occurred in 1839. A seafaring man had brought from New Zealand a solitary fragment of a long

bone, and wishing to find a purchaser he submitted it to Owen, who published a description of it, with the announcement that it had belonged to a gigantic bird allied to the ostrich family, but hitherto unknown to ornithologists. This surprising inference was at first received with some incredulity, but was amply verified in 1843 and subsequent years by the arrival in this country of complete skeletons of the extinct bird called "moa" by the natives of New Zealand and named *Dinornis* by Owen. In after years many strange anatomical queries were in all seriousness addressed to him, of which whimsical instances are recorded in the biography, perhaps the most remarkable being a personal inquiry made by the Chief Spoon and Ladle-maker to the Commander of the Faithful. This official brought from the Sultan's jewel-house to the Museum a most beautiful ladle, the bowl of which was of a fine horny material supposed to be the beak of the phoenix, and he explained that the object of his mission was to obtain accurate scientific information regarding this bird. Owen, however, after some research discovered that the bowl of the ladle was made from the beak of *Buceros galeatus*, a rare bird found in Ceylon.

Owen's great triumph in his later years was the creation of the magnificent Museum of Natural History at South Kensington. The space available for zoological specimens in the British Museum being altogether inadequate, he in 1859 "submitted a strong report to the trustees setting forth his views as to a National Museum of Natural History, accompanied with a plan." The scheme was considered by a committee of the House of Commons and was ultimately rejected, its foremost opponent being an Irish member, the representative of county Galway. In 1862 the scheme was again brought before Parliament, being introduced by Mr. Gladstone, as Chancellor of the Exchequer, but it was defeated. In 1863 Mr. Gladstone obtained leave from the House of Commons to purchase land for the building, and eventually eight acres of ground were acquired at South Kensington. The removal of the specimens from Bloomsbury to the new building at South Kensington was commenced about 1880 and occupied some years. In the end of 1883, being advanced in his eightieth year, and in the possession of almost all the honorary scientific distinctions which could be conferred on him, the enumeration of which occupies more than three pages of the second volume, Owen retired from his official duties in relation to the national collections of natural history. He had witnessed the complete success of his efforts in their behalf, and, as he himself wrote, felt that he could now depart in peace. Professor Flower was appointed to the vacancy, and Owen withdrew into private life with the dignity of K.C.B. and a pension, which was augmented at the instance of Mr. Gladstone. His declining years thereafter glided serenely away, until the peaceful arrival of the closing scene in December, 1892.

Three photogravure portraits of Owen at different periods of life are a material addition to the value of the narrative, two of them forming frontispieces to each of the volumes. The author has naturally found his theme congenial, and there need be no hesitation in predicting for his work a permanent place in the literature of biography and personal anecdote.

Pulse Gauging: a Clinical Study of Radial Measurement and Pulse Pressure. By GEORGE OLIVER, M.D. Lond., F.R.C.P. London: H. K. Lewis. 1895.

ANY means of increasing our reliable information concerning the indications for diagnosis and treatment afforded by the pulse ought to be, and no doubt will be, welcomed by the profession. In pulse gauging by the arteriometer and the pulse pressure gauge Dr. Oliver has at present a practical monopoly, for, although we believe instruments for gradually compressing the pulse to obliteration have been in use before,

the more elaborate and accurate instruments to which we have referred are of his own invention. Unlike the sphygmograph, which affords us information of a kind difficult to obtain by tactile methods, the instruments with which we are at present concerned are intended to afford more precise information concerning conditions which are often very fairly estimated by the time-honoured means of "feeling the pulse." Into feeling the pulse the personal equation no doubt enters very largely; the sensitiveness and intelligence of the individual are variable quantities. Mechanical instruments, on the other hand, ought to be more alike; but all such should, we think, before being sold to the profession, be tested, like thermometers, by comparison with a reliable standard. Otherwise the variation of man is introduced into the automatic machine. In the use of instruments, moreover, as in observation generally, there are sources of fallacy—many, no doubt, avoidable—which require to be well known to be eliminated. A knowledge of these only comes by experience and usually by the discovery of error. How *not* to do anything frequently precedes a knowledge of how to do it. The only justification for the multiplication of our means of observation, and for the substitution for our naked senses of mechanical aids, is the inadequacy of our present means and of our unaided senses to investigate the conditions for which such increased aid is introduced. In estimating the practical value of the work before us these appear to us to be considerations which must be borne in mind. They are not ignored by the author. While by the finger we can form a general idea of the size of the radial pulse, it must be admitted that its calibre can be more exactly measured by means of such an instrument as Dr. Oliver's arteriometer, and, this once exactly noted, an increase or diminution may be ascertained more certainly than if we trust to the memory of our impressions. This is important, as it has been found that the same vessel may under different circumstances vary in this respect, and evince peculiarities in disease which distinguish conditions of health from those accompanying a morbid state. Such peculiarities may be, and have been, determined without instrumental aid, but precision may be imparted to our conclusions by employing the arteriometer and pulse gauge. Whether such precision is of sufficiently great importance for practical purposes to bring this instrument into even such general use as the sphygmograph may be questioned; but that it may be of great value in scientific investigation and education is, we think, highly probable. Not only, however, as an instrument of precision in scientific investigation, but also as an instrument of practical utility in "selecting and adjusting remedial measures," has Dr. Oliver found his instruments serviceable. "The pulse instruments have specially demonstrated the great restorative value of such physiological agencies as recumbent rest, exercise, diet, massage, baths, and mineral waters." Such data could no doubt be attained by the experienced physician by tactile methods sufficiently well, but it is also probable that the less experienced observer could by instrumental aid gain truer criteria than by the use of the unaided finger. Just as the pleximeter and hammer of the student usually give place to the more convenient fingers when the examiner has learned to trust them, so, also, will the latter from their very convenience tend to supplant the ingenious and accurate instruments Dr. Oliver describes. As an aid to the education of the hand we believe they may be of great value, and as such the author acknowledges their utility. For fuller particulars as to the construction of these instruments and the general results of pulse gauging obtained by their aid we must refer our readers to the very handy little volume before us. The labour which has been bestowed in collecting data, the care taken in checking known sources of fallacy, and the intelligence and caution evinced by the author in stating his conclusions cannot be too warmly acknowledged. Dr. Oliver's

work, carried out largely, we understand, in the midst of the duties of active professional life, also demonstrates an improved truth—namely, that the harvest to be garnered by members of our profession in every sphere is truly great, and that well-equipped labourers cannot be too numerous to contribute each a fruitful sheaf towards the common store of useful material. Dr. Oliver's excellent work is such a sheaf, and we cordially commend it to our readers.

Lehmann's Medicin. Hand-Atlanten, Band vii. Atlas und Grundriss der Ophthalmoscopie und Ophthalmoscopischen Diagnostik. Mit 5 Text- und 102 farbigen Abbildungen auf 64 Tafeln. Von Dr. O. HAAB, Professor an der Universität und Direktor der Augenklinik in Zürich. (*Lehmann's Medicine.* Hand Atlases, vol. vii. Atlas and Outline of Ophthalmoscopy and Ophthalmoscopic Diagnosis. With 5 Illustrations in the Text and 64 Coloured Plates containing 102 Illustrations. By Dr. O. Haab, Professor at the University of, and Director of the Ophthalmic Clinic at, Zürich.) München: Lehmann. 1895.

THIS manual, which fully deserves its name, presents, in a cheap and compact form, a series of plates in which the characteristic features of the principal diseases of the fundus of the eye are very well given. Though perhaps not quite equal in finish to the plates illustrating the larger works on ophthalmoscopy, they are still so satisfactorily printed that the student may feel sure, if he is well acquainted with the aspects of disease as here presented, there will be very few forms of retinal lesion that will give him any difficulty to diagnose. Some of the plates, as those of optic neuritis with retinal hæmorrhage consequent on the growth of an orbital tumour and those of the changes of the fundus in pernicious anæmia, in albuminuria, diabetes, and pregnancy are very good. Every figure is preceded by a short descriptive account, and we append a translation of one of these that their length and character may be understood by our readers: "Fig. 39: Retinal trouble from a blow on the eye; Bertin's cloud; commotio retinæ; erect image, somewhat diminished. This disturbance of the retina, frequently observed after blows inflicted on the eyes with blunt instruments, was first studied and described by Bertin. The lesion is transitory, so that it is more distinctly visible the earlier the eye is examined after the accident. It is most frequently occasioned by blows with the fist or stick, or from stones or snowballs. In many instances, two quite distinct, milk-white spots may be seen on the retina, one of which is at the point where the eye was struck whilst the other is at the region of the macula lutea. The former is usually the larger, more pronounced, and more persistent of the two. The macula and the vision may be unaffected. The peripheric opacity does not, as a rule, conceal the retinal vessels. The appearances presented were formerly often mistaken for detachment of the retina from the choroid. The nature of the opacity has not as yet been satisfactorily made out. Our illustration was taken from an eye which a few hours previously had been injured by a blow with a snowball." We may add that eight of these hand-atlases have been published and that nine more are to follow.

Traité Pratique des Maladies du Système Nerveux. Par J. GRASSET et G. BAUZIER. 4me Edition. Montpellier: Camille Coulet. Paris: G. Masson. 1894.

THE two immense volumes, each containing over 1000 pages, which compose the latest form in which Grasset's classical work has appeared, really constitute a fresh work, and they are characterised by the great care in research, the graphic presentation of facts, and the firm grasp of clinical characteristics and details which have been a feature of all the previous editions. The work has been subjected to the most thorough revision, and much fresh material has been added so as to make it, as we

have indicated above, almost a new book. The scheme is a very comprehensive one. There are six parts in all, the first being devoted to Diseases of the Brain, the second to Diseases of the Spinal Cord, the third to Diseases of the Medulla Oblongata, the fourth to Diseases of the Membranes, the fifth to Diseases of the Nerves and Neuroses, and the sixth to an account of the Nervous Manifestations of General Diseases. Each part is divided into a series of articles, and each article is subdivided into chapters. Thus, in the third part, dealing with diseases of the bulb, the first article or division is devoted to an account of localised lesions, and of its two chapters, the first deals with hæmorrhage and the second with softening. The second article or division is concerned with inflammation of the bulb, and its two chapters have as their respective headings Labio-glosso-laryngeal Paralysis—the ordinary bulbar palsy—and Acute Bulbar Paralysis.

It is almost needless, and indeed it would be impossible in such an article as this, to do more than merely indicate the aim and scope of such a work as that under review. Anything like a detailed examination of its varied excellence would be out of place and unnecessary. It is sufficient to say that it more than maintains the high standard arrived at in its predecessors; that every chapter is a perfect mine full of the richest ore, and can be regarded not only as itself furnishing the views and experiences of the two eminent neurologists who are responsible for the book, but as also indicating to the reader the various other sources from which knowledge of the particular condition has been derived. The only subject to which we should have expected more space to be devoted is that of epilepsy, and it is, we venture to think, a pity that a fuller account of epilepsy and Jacksonian epilepsy should not have been furnished, and that the two diseases should have been separated, apparently through the exigencies of the classification adopted, and not placed together in the book. The pleasant and clear, if somewhat discursive, style in which it is written, the varied and striking figures and diagrams with which the text is illustrated, and the excellent tables and indices which are added to it, all combine with the matter itself to form a book which is at once a monument of industry and ability, and a valuable and reliable guide to all whose work leads them to the study of nervous cases and neurological problems.

New Inventions.

AN APPARATUS TO ASSIST IN THE ADMINISTRATION OF THE BATH.

In the report of a clinical lecture on the method of using the cold bath in typhoid fever, by Dr. William Osler,¹ he draws attention to the difficulties of lifting the patient out of the bath. In the case he describes the patient was given thirty-six baths. I recently had under my care a strong, heavily built man suffering from typhoid fever, and even with the aid of two nurses I experienced the greatest difficulty in lifting him into and out of his bath. I therefore had fitted to the bed an apparatus which answered my purpose. The legs of the sheers were tied to the foot of the bed, where they remained firmly in position. I attached a "luff tackle purchase" to either end of the crossbeam, and from the lower block of each purchase hooked the end of a common Indian hammock. By placing a sheet over the hammock and spreading both out flat on the bed the patient was able to roll on to them without inconvenience. Now, by the multiplication of power effected by the combination of pulleys the patient is raised off the bed with the greatest ease to the position shown in the illustration, and when suspended is readily pulled over the edge of the bed and lowered gently into the bath. In taking the patient out of the bath the pulleys are of great use. The hammock containing the sheet and patient

are raised clear of the surface of the water and retained in this position for a few seconds, to allow the sheet and hammock to drip into the bath until fairly dry. The patient is then raised to the level of the bed and gently pushed over the edge on to a rubber sheet, whence, after drying, he rolls to his original place at the further side of the bed, and the mackintosh, wet hammock, and sheet are removed. As the bath may have to be given frequently—i.e., in typhoid fever perhaps whenever the temperature is above 103° F.—it is very important to have some such means in private

practice by which two nurses, or even one, can give the baths without much trouble. I therefore trust that in bringing this apparatus before the members of the profession a valuable therapeutic measure may be rendered easy in those details of its application which so often mean the difference between success and failure. Any carpenter can fix together the beams necessary for the two pairs of sheers, and the whole can be placed in position within a couple of hours.

G. CALDWELL STEPHEN, M.D.

Evelyn-gardens, South Kensington.

"THE SENSITIVE FINGER COVER."

WE have received from the Manchester Novelty Manufacturing Company a little appliance which we can conceive may be of considerable practical value to surgeons and dentists. It consists of an indiarubber membrane fashioned into a finger cover, and so thin that for all practical purposes the sensitiveness of touch is retained. Many circumstances arise in practical surgery where examination by the finger is an absolute necessity, and in some of these circumstances, if the finger can be covered and yet no loss of "erudite touch" follow on the protection, considerable gain in personal comfort will accrue to the medical attendant, a fact which holds good to a marked extent in the practice of dentists. As a rule, and within certain limits, the fewer of such adventitious aids introduced into surgical practice the better, for their multiplication must always mean the multiplication of the sources of infection against which aseptic measures have to be taken; but the exploring finger is so frequently required in places where protection against the ills that might follow upon a tiny wound or of a crack in the skin would be very necessary that we have no hesitation in recommending these little finger-caps to the medical profession. We may add that we have tested them practically, and can report that the sense of touch is not perceptibly impaired by their use.

¹ The Medical News, Dec. 3rd, 1893.

THE LANCET.

LONDON: SATURDAY, JANUARY 19, 1895.

WE have already, through the promptness of our correspondents, been enabled to place before our readers, not only the programme of the proceedings taking place in Calcutta during the Indian Medical Congress, together with an official list of the communications received at headquarters which would be read or taken as read before the different Sections, but also a few assorted papers. This week we give an abstract of the presidential address delivered by Surgeon-Colonel ROBERT HARVEY at the inauguration of the Congress, and commence a full account of the proceedings in the various Sections, choosing for earliest issue the papers delivered before the Section of Medicine. As an eloquent exposition of the practical use of such a Congress as that which has just come to a conclusion, Surgeon-Colonel HARVEY'S words need no reinforcement. We commend them to our readers that they may see in them, as we do, unmistakable proof that the pioneers of sanitation in India form remarkable examples of our national energy, taking upon itself to act under circumstances where action would seem to a less resolute and less enthusiastic spirit absolutely hopeless.

There are many side issues, any of which, considered singly, might be considered to justify the holding of an Indian Medical Congress. From the purely scientific point of view a congress of medical men whose life work has been largely done in the East should result in the dissemination of knowledge of disease well-nigh invaluable—whether for what it is or for what it might lead to—to their Western brethren. There are questions constantly arising in scientific medicine—practical, clinical, and of the laboratory alike—which the discussions at such a congress might be expected to assist us to answer. Some are questions of fact. As an example: Who should and who should not, in view of his medical history, follow an occupation that would necessarily take him to India? Some are questions of theory. As an example: Do telluric and atmospheric conditions change the type of a disease, the cause remaining the same, and the differences being only due to the environment? And between these two typical questions fall numberless others, no less obvious and important, to which the deliberations of an Indian Medical Congress might help us to reply. To serve this purpose alone would be doing inestimably useful work. Again, from what we may term the medico-social point of view, the holding of an Indian Medical Congress is of the highest importance to us all. A large number of our countrymen, as well as a large number of Her Majesty's faithful subjects who are bound to us by the tie that they own a common rule with us, pursue their medical careers and live the whole of their medical lives in India practically separated from personal touch with all our work. They read of us a little and we read of them a little, but the little only serves to reveal to both how real the separation is. We know of the work they do, and we know

how splendidly it is done, but we only obtain such knowledge in an abbreviated and desultory form. It is good, then, that we should be able to gather from the proceedings at a congress holden in the capital of our Eastern Empire, in carefully prepared papers sent from all quarters of the realm, a bird's-eye view of the position of medicine in India at the present day—good from the point of view of fellowship as much as of learning. And again we may say that if the Congress served this purpose alone it would be doing inestimable work.

But Surgeon-Colonel HARVEY placed the whole matter on higher grounds than any of these when he chose as the subject of his presidential address the sanitary needs and aspirations of India. The diffusion of knowledge counts for much, the establishment and maintenance of a wide professional sympathy counts for more, but the public health of our enormous Indian Empire counts for most. The progress that has recently been made in this direction serves only to show and to bring into a more prominent position the acute need for further work. Thirty years ago sanitary work was undreamt of in India. None of the means that now exist for grappling with the periodic visitations of famine and epidemic disease had been discovered; while the distinct caste systems and the common fatalism made the inhabitants of the country positively averse to taking any steps towards the amelioration of their unhygienic conditions. Thirty years have seen immense changes in every direction, in the face of difficulties which no one who has not sojourned in India would be able to appreciate; yet the Indian wants, in the words of Surgeon-Colonel HARVEY'S apt quotation, "most everything" sanitary. His hut village is built regardless of all hygienic rules as to its site or ventilation; he lives with his live stock and drinks from the pond in which they wallow; and if he should chance to have a well he places his dung-pit in juxtaposition to it. It is in a country more than half as large as Europe where such general conditions prevail that Surgeon-Colonel ROBERT HARVEY cheerily pleads the cause of sanitation. And, before all things, this is the cause the Congress should most advance, and a better one no congress could have. In spite of the almost insuperable difficulties progress has been made, and we know that it will be made. But let us in England give some measure of thought to what the task has meant and will mean to those who are carrying it out.

We heartily congratulate Dr. W. J. SIMPSON and Surgeon-Captain D. M. MOIR on the successful termination of their arduous labours as secretaries of the Congress.

THE question as to what is the best treatment in cases of fibroid tumours of the uterus is one of considerable and very general interest, for such tumours are among the commonest morbid conditions met with in the class of diseases peculiar to women. It will be as well, in order to avoid misapprehension, to define a little more clearly the group of cases the treatment for which we especially propose to consider. To begin with, we may at once dismiss cases of fibroid polypi and cases where the interior of the uterus is occupied by a fibroid so far projecting into it that but little of the growth remains embedded in the uterine wall—where, that is to say,

although there is not actually a polypus, yet the attachment of the fibroid is very limited and superficial. In such cases all competent authorities are agreed that removal of the polypus or tumour is the proper treatment, and at the present day the operation, skilfully performed with all antiseptic precautions, is almost free from risk. It is not with cases of this kind that we are at present concerned, but rather with all the others, these only excepted. Let us take, for example, a case of fibroids where the uterus is enlarged, so that it reaches as high as the level of the umbilicus, or higher; where, after dilatation of the cervix, it has been ascertained that there is no submucous fibroid capable of being safely removed per vaginam; where the symptoms commonly met with in such cases are well marked, more especially menorrhagia, dysmenorrhœa, and pressure symptoms, varying in severity with the size or position of the growth; and where, besides, the usual medical treatment of a palliative nature has proved to be unsatisfactory. What is the proper treatment? The answer to this question will become apparent if we sketch briefly the history of the operative treatment of uterine fibroids since the year 1855. We believe that the first hysterectomy for fibroid tumour of the uterus which was deliberately undertaken was successfully performed in that year by KIMBALL in America. After tying the broad ligaments he transfixed the cervix and tied on each side, leaving the ligatures long and hanging out of the lower angle of the wound. A glass drainage-tube was used. Although this case did well, two other patients on whom he operated died. Then came the era of the extra-peritoneal method, in which the stump was clamped and fixed outside in the abdominal wound, an era especially associated with the names of KOEBERLE, PÉAN, and KEITH. The general adoption of the intra-peritoneal method of treating the pedicle in ovariectomy soon led to many ingenious attempts to apply the same principle to the stump after supra-vaginal hysterectomy. The very multiplicity of these methods goes to show that no one of them proved to be really satisfactory, and in fact none of these earlier methods were found to provide adequate security against secondary hæmorrhage occurring from the stump. Meanwhile the removal of the uterine appendages in cases of fibroid tumour was introduced with the object of bringing about as a result of the operation those retrogressive and beneficial changes that occur in a certain number of patients with fibroid tumours after the natural menopause. This operation, which is not possible in many cases, and which in many others is not entirely satisfactory in its results, has yet, and as it were under protest, held its place up to the present time. Quite recently Dr. CULLINGWORTH published an important contribution to the literature of this operation in the St. Thomas's Hospital Reports, in which an account is given of twenty cases of fibroid tumour in which he removed the uterine appendages. The conclusions at which Dr. CULLINGWORTH arrives as regards the operation are, among others, that it affords an almost certain means of relieving all the more dangerous pressure symptoms in cases in which active treatment is necessary and where the removal of the tumour is either impracticable or very dangerous. He considers it to be unsuitable in cases where the tumours have attained

a very large size, or have become cedematous, or have undergone cystic or other changes. He also thinks that the field for this operation will become still further restricted in proportion as the technique of abdominal hysterectomy improves, and its mortality in consequence diminishes. In fact, we may say with a recent American writer (Dr. BALDY) that the removal of the appendages for fibroid tumour must be considered "an incomplete operation with a limited application." We may undertake it when we do not feel justified in performing the operation that promises more complete and immediate relief—that is, supra-vaginal hysterectomy. Many prominent operators in America and on the Continent have gone a step further, and now practise total extirpation of the uterus in cases of uterine fibroid, in this way avoiding any question of the extra-peritoneal or intra-peritoneal treatment of the stump. CHROBAK reported seventeen successful cases of total extirpation for fibroids. His operation consisted of two steps—first the supra-vaginal amputation of the uterus, and then the removal of the cervix. Since then he has, we believe, given up the latter step, and now only removes the supra-vaginal portion of the uterus after ligature of the uterine arteries. We should be disposed to regard this as the ideal operation, and to look upon total extirpation as unnecessarily radical, especially as the operative procedures involved in removing the cervix are by many considered as more difficult than those needed for the other and more essential part of the operation. There can, at all events, be no doubt that total extirpation weakens the pelvic floor and produces a greater disturbance of the natural relations of the vaginal fornices, besides which there is the additional risk involved in placing the vagina in communication with the peritoneal cavity. The truth really is that total extirpation for fibroids was introduced with the view of avoiding the risks—especially of secondary hæmorrhage and sloughing—believed to be inseparable from leaving the stump of the cervix when treated by the intra-peritoneal method of SCHROEDER and his followers, and ligaturing it *en masse*. It has now been shown that, by tying the uterine arteries before amputating the body of the uterus, the danger of secondary hæmorrhage may be avoided, and, further, that so long as no sutures or ligatures are passed into the tissues of the cervix itself, and no dilatation, scraping, or cauterising, or, indeed, any interference, is employed as regards the cervical canal, and also provided that the peritoneal flaps are sutured over the stump, there is little or no risk of infection to be feared from that direction. To Dr. BAER of Philadelphia largely belongs the credit of perfecting this method and describing the details of the technique in such a manner that the operation by his method may be clearly understood and practised by others; though Mr. MILTON of Cairo reported in the columns of THE LANCET¹ cases operated on by a method very similar to that employed by Dr. BAER. Last year Dr. BAER was able to report that he had performed thirty-four abdominal hysterectomies by his method of intra-peritoneal treatment of the pedicle, with only two deaths. As such a series of successful cases is sufficiently extensive to eliminate the influence of mere good fortune

¹ THE LANCET, Nov. 29th, 1890.

we cannot do otherwise than conclude that the method by which such a result has been obtained must be based on sound principles. A mortality of less than 6 per cent. in a series of thirty-four cases speaks for itself. We have little doubt that Dr. BAKER's method of abdominal hysterectomy for fibroids will eventually be much more frequently undertaken in this country. Though no series of cases such as his own has yet been published from among the cases of operators in England, we understand, nevertheless, that several operations according to this method have been performed in London with good results, and no doubt we may expect before long that an account of them will come before the profession.

THE determination shown by the Cork medical men in the matter of clubs is far more than a local matter. We are not always accustomed to regard Irishmen as examples of cohesion and organisation. The sharp differences of race and religion in Ireland and the warmth of the national temperament readily lend themselves to differences and even to discord in action; but here is a body of men, numbering nearer seventy than sixty, practically unanimous and acting as one man. Besides their unanimity there is another secret of the strength of their position—viz., the reasonableness of their demands. They ask that the club system shall be restricted to those for whose convenience it was originally created. If the profession in Cork were insisting on terms which would embarrass the decent poor they would have no sympathy from either the public or the profession. Medicine is not a luxury as law is in a certain sense; it is essential and indispensable. The poor man and the poor man's wife and children need it as much, and in some respects more, than the rich man. Medicine has to do for the poor what comfortable circumstances and pleasant holidays will sometimes do for the rich. Its aid is so indispensable that if it cannot be paid for it must be given gratuitously or provided by the State. So true is this that the poor run to the medical man as to a kind of providence at all hours of the day and night, and have so regularly been met by him in a spirit of kindness and humanity that it has come to be almost forgotten that he is a man with many wants, whose education is costly and whose work is more so. This mistake is to some extent corrected by the club system. The wage-earning classes have many members who employ their own private medical man with great advantage to themselves. They pay him fees proportionate to their means rather than to the value of his services; and he is pleased to have such patients. But, obviously, it is right in this indispensable profession to make arrangements with the wage-earning classes for attendance on terms of accommodation. This is done everywhere. And everywhere it is found liable to abuse. Persons, and whole classes of persons, who are perfectly able to pay the ordinary charges for medical attendance, join the clubs and take advantage of terms which were meant for others. The very fact that one of the new rules objected to in Cork is that the wage limit for medical attendance in clubs shall be £200 is significant of the enormous abuse—we had almost said demoralisation—to which the system has led. We should have thought that any family whose joint income was £200

or over would have made it a point of honour to have a private medical man and to pay him adequate fees. That bankers, vintners, shipbuilders, and merchants of all sorts should have taken the services of a club medical man on club terms, and think it consistent with Irish honour, could not have been anticipated. The wonder is, not that the medical men of Cork are now resisting such arrangements, but that they have borne with them so long. They may feel assured that they have the sympathy of the whole profession in the stand which they are at present making. It would be wrong to doubt that many of the comfortable and well-to-do classes who have abused the club system of Cork have done so thoughtlessly and without intending to be shabby to a great profession. But the present crisis in Cork removes this excuse. They now know that they are in a false position and that they have duties and debts to medical men which cannot be discharged on club terms. They will find medical men entirely reasonable, not expecting the impossible or the impracticable, but expecting, on the other hand, that which is their due.

The encouragement of medical practice is the duty of every citizen who has it in his power. In encouraging medical practice he is encouraging medical science, and this is a duty binding on every member of a civilised community. We are unwilling to believe that any intelligent citizen will refuse to admit this, or will deny our right as medical journalists to hold high the claims of medical men to be treated with individually and on terms corresponding to the special education they bring to the service of a community. And our right is also indisputable to point out to all members of the medical profession that this movement in Cork has a claim to their help and sympathy. It is said that the younger members of the profession there are working with perfect faithfulness to the principle involved and with much self-sacrifice. It is a temptation to them to profit by the faithfulness of others; but they have shown themselves above all such temptations. All honour to them. The duty of outsiders in such circumstances is obvious. Is the medical profession to be the only one in which there is to be no *esprit de corps*? May men come from Dublin and London and Belfast and take the places of those who are making a stand for the most reasonable rules? To put such questions is to answer them. Let no man who does so imagine that he is doing a good or a noble thing. This is a domestic quarrel in Cork between those who perfectly respect each other, and nothing in medical ethics is more clear than that the stranger who interferes is disloyal to his profession.

THE agitation in favour of the new scheme proposed by the Royal Commissioners for a reconstitution of the University of London, so that it may become a local Teaching University for London as well as an Imperial Examining Board, has again come to the front. On Tuesday next, the 22nd inst., at noon, a deputation from the various bodies which have expressed a general approval of the scheme will wait upon the Premier and urge upon him the desirability of appointing a statutory commission to frame statutes and ordinances in general conformity with the report of the Gresham Commission. Later another deputation,

consisting of graduates who think that if a local Teaching University for London be desirable it ought to be constituted apart from the existing University of London, will also be received by the Premier. He will thus have the great advantage of hearing both sides of the question in virtual simultaneity: that of the teachers anxious to enlarge the scope of the existing University, and that of the graduates who are naturally anxious that the prestige of their degrees should not be lowered, as is possible by the proposed changes. By a curious coincidence the next meeting of Convocation of the University is appointed for the same day at 4 P.M., and the members thereof will be occupied with the same business.

On May 8th, 1894, it will be remembered, Convocation adjourned after the whole question of the constitution of the University had been referred to the Annual Committee, with power to nominate members of a joint consultative committee of the Senate and Convocation. But owing to a technicality it was afterwards found that any nominations made by the new Annual Committee might be objected to as invalid, and so the resolution was not acted on. Four delegates, however, attended the meeting at the Royal College of Physicians of London on June 30th, 1894, and agreed with almost all the delegates representing the various institutions affected by the scheme in strongly advocating the appointment of a statutory commission at an early date. And there the matter stopped. It is clear that a statutory commission might be either a purely ministerial one, and would then only deal with the scheme as it stands, or one invested with wider powers, and these might be so large as even to reopen the whole question. Considerable difference of opinion exists among the various bodies interested as to what the extent of these powers should be, and we shall wait with some anxiety to see if Lord ROSEBERRY gives any clue as to his own views on this material point. If these are forthcoming for the meeting of Convocation in the afternoon they will undoubtedly greatly affect the attitude of Convocation towards Dr. SYLVANUS THOMPSON'S first resolution, which reads thus: "That Convocation is of opinion that there should be one University in London and not two; and that the interests of higher education will be best served by such an enlargement and reconstruction of the existing University as will (while retaining its existing powers and privileges and without interfering with the efficient discharge of its present duties as an examining body for students from all parts of the British Empire) enable it to promote learning, scholarship, and research as a Teaching University for London." But the scheme of the Royal Commissioners involves such a reconstitution of the present University of London that its existing powers and privileges must be largely destroyed should their recommendations be acted on by a statutory commission; whereas if full latitude is given by Parliament to such a commission a very different scheme might be the outcome of its deliberations and decisions.

MISS L. B. ALDRICH-BLAKE, M.B., B.S. Lond., has been appointed anaesthetist to the Royal Free Hospital by the weekly board of that institution, in succession to Dr. Silk, who has resigned.

Annotations.

"Ne quid nimis."

INQUESTS WITHOUT MEDICAL WITNESSES.

AN example of the injudicious practice of dispensing with medical evidence at inquests has just occurred at West Hartlepool. The inquiry was as to the cause of the totally unexpected and painfully sudden death of a gentleman in a club. Having risen from his chair in order to get a newspaper, he, without any warning, fell heavily on the floor, whereby his right cheek was very severely cut and bruised. The other members rendered what assistance they could, and a medical man who was summoned arrived in a few minutes; death had, however, already resulted. An inquest was held on the following day, at which it would seem that the only witnesses called were the deceased's brother-in-law, and two members of the club who witnessed the event. According to the *Northern Guardian* the jury asked if it was necessary to have the medical attendant's evidence, to which the coroner replied, "Certainly not, unless you want to spend the ratepayers' money." The jury thereupon returned a verdict of "Death from natural causes." The proceedings appear to have been of an altogether formal character, and to have contributed nothing towards that explanation of the cause of death which is the chief aim and object of an inquest. Of course, there was in this case a complete absence of foul play, but the anxiety of many coroners to dispense with the expression of medical opinion at their inquiries, except under the pressure of obvious necessity, distinctly tends to diminish the value of an inquest as an institution designed for the information and protection of the public. In THE LANCET of Nov. 24th, 1894, mention is made of an inquest on the body of an epileptic in which the principal witness seems to have been a police constable, who deposed that death was due to epilepsy. As the body of the deceased had been found lying face downwards on some manure it is clear that suffocation during a fit was at least a more probable cause of death than epilepsy itself. Inquests conducted in such a fashion obviously can serve no useful purpose, and are not likely to secure either the confidence or the respect of the general public.

GROCERS' LICENCES.

MR. DAVID A. THOMAS is about to again introduce a Bill into Parliament for the abolition of grocers' licences. This has reopened, notably in the columns of the *Times*, the vexed question involved by the sale of intoxicants at grocers' shops. From the first THE LANCET pointed out that the sale of wines, spirits, &c., by grocers would encourage, facilitate, and sometimes even engender secret drinking. Mr. John Hilton, of the Alliance London Office, quotes our report of July 7th, 1877, when, in answer to questions we had addressed to the medical profession on the subject, 917 physicians and surgeons signed a statement declaring their "strong persuasion that the facilities for obtaining spirits, wines, stout, and ale in bottles provided by the grocers' licences have a most injurious tendency," and that "women, servants, and children of respectable households who could not or would not procure intoxicating drinks at public-houses are encouraged to purchase and use these liquors by the opportunity offered when visiting the grocer's shop for other purposes." To these well-known facts Mr. John Hilton, in his letter to the *Times*, adds a new and hopeful feature to the controversy. It appears that grocers' licences are not so profitable as they were naturally expected to be. Indeed in some cases they have been the cause of

absolute failure. If so, the chief obstacle to their abolition will disappear. One grocer is mentioned as being ruined after he took out a wine and spirit licence. His customers contracted drunken habits, opened quarterly accounts, which they often failed to pay, while his shop assistants drank his wine and neglected their work. Another shop with two large windows—one devoted to groceries, the other to wine and spirits—had ruined two successive proprietors. A third purchaser presented himself, but only on the condition that the liquor was removed. This was done, though thought to be an act of madness; but the result has been the creation of a prosperous and profitable business. At a third grocer's shop, where the liquor traffic had also been abandoned, the net profits had considerably increased. It would seem that among customers who buy liquors with their groceries the proportion of bad debts is much higher. If this experience is confirmed in other quarters a great step towards the abolishing of grocers' licences will have been taken. Such questions should be settled purely on moral grounds; but if it so happens that the material interests of the trade will not be as disadvantageously affected as was generally imagined, we shall be all the better pleased. We have no reason and no desire to attack the interests of the grocery trade, but it is our duty to denounce all that encourages or facilitates alcoholism and thus endangers public health.

GEORGE RAINEY.

ALL St. Thomas's men whose recollection of the hospital extends back for fifteen or twenty years preserve kindly memories of Mr. George Rainey, the veteran demonstrator of anatomy. Unconventional in exterior, he was largely endowed with sterling qualities of head and heart, acknowledged even by the light-hearted young men who learned from him to trace out and understand the intricacies of their "parts." Most teachers know how arduous a duty is the unrelaxing effort to awaken and sustain a student's interest in his work, and to lead him to an intelligent comprehension and recollection of it, especially in a field so wide and so full of details as anatomy. Rainey's success in this direction was recognised by all who came in contact with him, including the dignified seniors who uphold the high position of St. Thomas's Hospital among schools of medicine. In addition to his work as an instructor Rainey carried out much original investigation. THE LANCET in 1851 contained an elaborate and thoughtful paper¹ written by him on the adjustment of vision effected by the ciliary processes and the pecten. Many other original memoirs by him appeared in the Annual Reports of St. Thomas's Hospital, the Transactions of the Royal Medical and Chirurgical Society, the Transactions of the Royal Society, &c. His first important paper was on a botanical subject—the Ascent and Descent of the Sap. It was read before the Royal Society in 1842 and appeared in book form with some additions in 1847. Botany and physics were combined in an investigation on the Formation of Starch Granules, the results of which were read before the British Association in 1859. In conjunction with his duties as demonstrator of anatomy he held a position as a practical microscopist which was at that time almost unique. Fifty years ago the microscope was in the hands of trained specialists only, and was far from being reckoned, as it now is, one of the ordinary accessories of a medical education. Rainey was an adept in microscopical manipulation and demonstration as then practised. Transparent injections were not at that time in use, but his specimens of tissues injected with opaque materials were a marvel to his contemporaries, and are

valuable even now. By means of them he discovered the nature of those structures in the synovial fringes which have been called "Rainey's bodies," and which are now known to be the starting point of loose cartilages in joints. The *Quarterly Journal of Microscopical Science* and the Transactions of the Microscopical Society contain papers by him on the Cutaneous Follicles of the Toad and on Methods of Illumination in Microscope Work. His laborious life was prolonged far beyond the usual term. Born in 1801 in Spilsby, Lincolnshire, he came to London in 1824, and became a student at St. Thomas's Hospital. In 1827 he qualified as M.R.C.S., and obtained great success as a private teacher of anatomy. His tutorial connexion with St. Thomas's Hospital commenced about 1844, and continued for about forty years, being terminated only by his death in November, 1884, in the eighty-fourth year of his age. For this sketch of his career of active usefulness we are indebted mainly to an appreciative article contributed to the St. Thomas's Hospital Reports by his friend Mr. Wagstaffe, late senior assistant surgeon and lecturer on anatomy at the hospital.

PRESENTATION TO LORD SANDHURST.

THE important services rendered by the Right Hon. Lord Sandhurst to the Middlesex Hospital as chairman of the weekly board for the last six years have been gracefully acknowledged by his colleagues in the governing body, in conjunction with the medical staff and the resident officials. His lordship, who has been appointed Governor of Bombay, necessarily vacates his official position at the hospital, and was on the 12th inst. presented with an address together with a bowl and four goblets in silver. An influential gathering of the subscribers to the testimonial assembled to meet his lordship, the presentation being made by Mr. J. Bell Sedgwick, deputy-chairman of the board, supported by Mr. J. W. Hulke, President of the Royal College of Surgeons of England and senior surgeon of the hospital. Mr. Sedgwick delivered a very complimentary speech, to which Lord Sandhurst replied in appropriate terms, assuring the company of the regret with which he retired from his congenial duties at the hospital.

INFANT NEGLECT, INSURANCE, AND MORTALITY.

THE more closely we examine the practice of child insurance the less there appears to commend it. Notwithstanding the fact that disease is much more prevalent during the early years of life than later, it by no means follows that death is an equally certain factor in the table of probabilities. Well tended, well nourished, and within reach of prompt and skilful medical service qualified by no exorbitant fee, the prospects of infant life even among the poor, if they be careful also, are hopeful in a high degree. Life, not death, is the natural outlook, and the necessity for insurance is proportionately less. The social status of so young a child, moreover, as a rule is absolutely trivial. Compensation for its death argues a loss which is incalculably small. We cannot, therefore, find in such reasons as these facts afford any real justification of the system of insurance. Nor is the position of those who would advocate this system greatly improved when we pass to the question of ways and means as connected with the event of an infant's death. Simple in the extreme are all the needful arrangements for a funeral. Their cost would not overtax the slender means of almost any family which is maintained by honest work and thrift, so that even from this point of view insurance has somewhat the aspect of a superfluity. It is to be noted also that very many of those parents who pay their weekly contributions in token of their prudent fears are at the same time distinguished by a neglect of their offspring and a self-indulgence which are not less than criminal. Among 4629

¹ THE LANCET, July 26th, 1851. On the Function performed by the Ciliary Processes and by the Pecten in the Adjustment of the Eye to Distinct Vision at Different Distances.

children subjected to cruel treatment during the past month it is reported by the organ of the National Society for their protection that 1237 were known to be insured. So, too, was an unfortunate infant whose death was recently investigated by the coroner for the West Middlesex district. The parent could not afford medical aid (which he might have had for a mere pittance), but he did not neglect to pay his insurance premiums. Facts like these tend to sicken the public conscience. They strongly suggest a necessity for drastic reforms in a system of somewhat doubtful and limited advantage. Among such reforms we should, for our own part, insist upon two at least—namely, that the sum insured should no more than discharge the bare cost of funeral arrangements, and that evidence of such criminal neglect or mismanagement as might account for a child's death should disqualify for the receipt of the sum insured. Medical practitioners have a special duty in this connexion, and ought to be scrupulous in refusing to grant the customary death certificates in cases where they believe that such mismanagement has occurred.

CONSERVANCY AND WATER CARRIAGE SYSTEMS FOR THE REMOVAL OF EXCREMENT.

DR. BOOBBYER has presented to the health committee of the town council of Nottingham a valuable contribution to the literature bearing on the important subject of excrement disposal in large urban centres. The report is primarily intended to aid the committee in considering their future attitude towards the existing pail system in the borough; but it seems to be suited to the necessities of many towns where a like system obtains and where the sanitary authority are desirous of securing for their town competent advice given as the result of knowledge of the methods in vogue in a wide variety of places and circumstances. Dr. Boobyer's report covers a wide area, being based on information obtained from seventy-eight towns (including the "great towns") of Great Britain and Ireland, a comprehensive tabular statement making his deductions all the more useful. Briefly stated, there is a general discontent with the conservancy system—the midden privy, pail closet, cesspool, and so on—only four towns openly advocating it—namely, Darwen, Hull, Warrington, and Rochdale—the latter for many years famous for the "system" to which it has given its name; but the opinion of these towns is far outweighed by the general condemnation resulting from experience in the other towns where the air, soil, and water-polluting conservancy methods find tolerance. One interesting fact given is that the nightsoil from the 40,000 pail closets and the 500 privies in Nottingham amounts annually to 500 tons, these figures permitting of an estimate for other places in like circumstances. Replies from forty-two large towns were strongly in favour of waterclosets both for in-door and out-door use; but the question of frost is not overlooked in regard to the latter use of waterclosets, though the damage so caused seems to be less than is popularly supposed. Dr. Boobyer treats also of slop-water and trough closets, in favour of which Dr. Parsons has already some time back reported to the Medical Department of the Local Government Board, although the advantages of these forms of closet are not without some counter drawbacks, choking and difficulty of cleansing being among the latter. But, again, slop-water closets admit of being readily converted into waterclosets. At any rate, twenty-three towns look upon these forms of excrement removal very favourably, extended adoption leading to more pronounced views in their behalf, the tipping basin being the most generally adopted form of flush, and a three-gallon flush being regarded as a desirable minimum. One important point touched upon is that several towns offer a subsidy in aid of the conversion of dry to water carriage systems,

Stafford proposing to offer as much as £3 in regard to each obsolete closet so converted. There is satisfaction in learning that in only three towns is the objectionable cesspool in wide use; but what is of very serious moment is the fact elicited that no fewer than fifteen of the larger towns—excluding London—with an aggregate population of some 2,750,000 inhabitants, discharge the bulk of their sewage in a practically crude state into inland waterways. Truly the Rivers Pollution Prevention Acts have been anything but that which their name implies, in so far as only too many of our populous towns are concerned. The matter calls for the earnest attention of county and parish councils and for the formation and sustained action of joint committees for the suppression of the pollution of our rivers. For the rest, Dr. Boobyer shows the superiority of the watercloset for general indoor use and the desirability of automatic slop- or waste-water closets in poorer neighbourhoods and for outside use, though these latter, equally with trough closets (which, by the way, are liable to injury by frost), call for supervision by a staff of men attached to the Health Department. Trough closets, however, require a special (clean) water-supply, unlike the slop closet, which is self-feeding from the liquid waste of houses. We commend Dr. Boobyer's report to all sanitary bodies interested in the question of excrement disposal. It is written in a lucid style and contains valuable standing matter for reference in its tables and summary.

THE NATURE AND TREATMENT OF LEPROSY.

AN interesting article on the above subject appears in the *American Journal of the Medical Sciences*, by Dr. R. H. L. Bibb, who has examined thirty cases of tuberculous and five cases of macular leprosy with reference to the presence of bacilli, and has never failed to find them in sections of tubercles, in blood drawn directly therefrom, in discharges from leprosy ulcers, and occasionally in the sputum and the secretions from the nose; but he has never found them in the faeces, urine, or blood, except when the latter was taken directly from a tubercle, although other investigators—Kübner, according to Thoma and Cantlie—claim to have found them in the blood current. After referring at some length to the opinions of different writers as regards the nature of the bacillus and the question of heredity and mode of spread of the disease, Dr. Bibb discusses the treatment of leprosy. He has during the past ten years employed a great many drugs in treating a great many lepers; and while he has seen some truly marvellous results—results he was in nowise prepared to witness—follow the use of certain measures, he is not prepared to assert positively that he has brought about a radical cure of a single case of leprosy in either of its stages. Preparations of arsenic, mercury, and iodine when the disease was not associated with syphilis—it is often thus associated—he has found to be worse than useless; but he has seen very marked improvement in all three stages of leprosy follow the systematic use of Chaulmoogra oil internally and locally (associated with an improved dietary and personal hygiene), and this in a sufficient number of cases to induce the belief that while in no sense a specific, as regarded by Bergé, if commenced early in the disease and continued long enough and unintermittingly and associated with proper food and hygiene, it will cure the patient in many instances. Of course, there are many cases it will not benefit, probably a large majority, but Dr. Bibb has never seen it properly used without notable improvement ensuing, especially in the tuberculous stage. He has seen tubercles absorbed, anaesthesia removed, eruptions disappear, ulcers heal, pains quieted, suppleness and elasticity of the skin restored, and hope take the place of despair under its use. He begins treatment with ten drops of the

oil in gelatine capsules after each meal, to be taken with a glass of milk, the quantity to be gradually increased until from one to two drachms of the oil are taken daily, but few patients can take as much as two drachms daily without suffering from diarrhoea. At the same time the patient is bathed every second day with warm water and soap, and the oil is warmed and well rubbed into the skin over the entire body, including the ulcers and maculae.

THE INFECTIOUS DISEASE (NOTIFICATION) ACT.

IN view of the constant requests we receive for advice as to difficulties under the Infectious Disease (Notification) Act—and the number of cases where difficulties have arisen has become considerable and shows no sign of abatement—we have prepared a statement embodying the decisions and published opinions of the Local Government Board on this subject, a first instalment of which will be found on p. 171 of our present issue.

DEATH UNDER NITROUS OXIDE GAS DUE TO TIGHT-LACING.

MORE than one fatality from tight-lacing has recently been noticed in our columns. In all conditions in which free respiration becomes a necessity if the vital processes are to be carried on tight-lacing means death. Of all states that in which a patient takes an anæsthetic is the one when absolute freedom of breathing is a necessity. Unhappily, but few know this elementary fact in physiology, and hence the sad death of a girl who had taken nitrous oxide gas at a dentist's rooms, and while recovering from its influence had a fatal attack of syncope. The statement is made that her stays were five inches too small for her natural body, a disparity of shape which we imagine the dentist might have seen and acted upon before he ventured to give the unfortunate girl nitrous oxide gas.

THE METROPOLITAN WATER SUPPLY DURING DECEMBER, 1894.

DR. FRANKLAND, in his December report on the condition of the London water supplies, states that on Dec. 10th the Thames at Hampton was turbid and pale yellow in colour, but otherwise it was chemically in excellent condition. Bacterially the same water was of very inferior quality. As delivered by the five companies drawing their supplies from the Thames the water was in every case efficiently filtered, though owing to the previous impounding of flood water it was, on the whole, less pure organically than the untreated river water passing the intakes at the time the samples were taken for analysis. The bacterial improvements effected by the various Thames companies ranged from 99.21 per cent. in the case of the Grand Junction to 99.96 in the case of the West Middlesex. The water as delivered both by the New River and the East London companies was efficiently filtered, but it was slightly inferior to the unfiltered water in respect of organic purity. The bacterial improvement averaged 99.39 per cent.

THE DIFFUSION OF SMALL-POX.

IN London there was a slight increase in the number of small-pox attacks last week, these being 11, whilst 8 were admitted to the institutions of the Metropolitan Asylums Board, leaving 28 patients under treatment. Birmingham was free from fatal cases last week, but experienced fresh attacks to nearly a score, 13 cases being admitted to hospital, leaving 67 therein at the close of the week, some neighbouring districts also having suffered invasion. There were 3 registered deaths in Liverpool, where small-pox has shown a slight disposition to increase, some score of attacks occurring, and the adjacent borough

of Bootle would seem to have had cases also last week, several being reported towards the close. In Edinburgh there were 15 registered deaths last month, with a serious recrudescence of the disease, which was fatal to the extent of 3.4 per cent. of the total mortality. Glasgow has during the present month had experience of the malady, but prompt removal of the patients to hospital has, it is hoped, stayed the disease. Dublin, after a heavy fall in the number of admissions to hospital from 113 to 32 in the concluding fortnight of December, had again an alarming increase in the first week of this month, no less than 71 admissions being chronicled, with 16 deaths. Of the 5 registered deaths 2 of adults were in vaccinated persons, and the remaining 3 in young persons all unvaccinated, aged respectively five weeks and twelve and sixteen years. The close of the week found 170 patients under treatment, exclusive of 121 convalescents.

DR. THOMAS GORDON HAKE.

THE connexion between medicine and letters—a connexion which an abstract of an interesting paper¹ by Mr. Simeon Snell printed in our columns recently showed to be not so rare as is generally supposed—was not much exemplified in the work of the late Dr. Thomas Gordon Hake, the poet, for, roughly speaking, Dr. Hake never practised at all, and, unlike Dr. Oliver Wendell Holmes, he made no use of his medical knowledge in his beautiful and imaginative verse. Dr. Hake was a personal friend of the late Dante Gabriel Rossetti and Mr. Algernon Charles Swinburne, and for these reasons, if no other, will always be classed in the popular mind as a pre-Raphaelite; but he took no active part in the promulgation of the tenets of that remarkable band of successful revolutionaries. Yet the titles alone of some of his poems, "The Serpent Play: a Divine Pastoral," and "Maiden Ecstasy," for example, show that he derived his inspiration from similar sources. Dr. Hake was considerably older than Rossetti, having reached the age of eighty-six when he died on Friday last (Jan. 11th), and was in enjoyment of a Civil List pension in recognition of his merit as a poet.

HOSPITALS AND PORT DUES IN THE EAST.

THE Chamber of Commerce of Liverpool has petitioned the Foreign Office for British shipping to be relieved of the hospital dues paid at the ports of Constantinople and Smyrna. It appears that Her Majesty's Consul-General at Constantinople levies dues on British ships at the rate of about one-third of a penny for every registered ton, so as to defray the cost of the British Seamen's Hospital in that city. This brings in about £5000 a year, but the hospital does not cost more than £3000 annually; consequently, since 1888 a surplus of about £14,000 has accumulated. At Smyrna the hospital tax is equal to 1½d. per ton, bringing in an average of £1414, and the Smyrna hospital costs an annual average of £1079, so it is reckoned that a surplus of £1900 is in hand, thus making, for the two ports in the space of five years, a saving of £18,000. Under these circumstances, and considering the very severe competition from which British shipping interests suffer, it is urged that the hospital dues actually levied in these two ports should be reduced or abolished. In this matter we have at present before us only one side of the question. We are very pleased indeed to hear that so large a reserve fund has been accumulated. This speaks well for the management of these hospitals, and it suggests that there is some useful scheme to which these sums will be ultimately applied. Galata is one of the most unhealthy quarters of Constantinople, and we know that at Smyrna it is proposed to remove the

¹ THE LANCET, Dec. 8th and 15th, 1894.

hospital to a healthier position outside the town. Undoubtedly, when we consider how totally devoid both Constantinople and Smyrna are of anything approaching to a drainage system and proper sanitation, it becomes more than ever necessary to carry patients out into the open and away from the foul emanations of undrained Eastern towns. Of course, there should be near to the port a small ambulance or receiving hospital for emergencies, accidents, and perhaps for the convenience of out-patients; but the majority of the cases undergoing anything like a lengthy treatment would derive great benefit from the purer air outside the town. The Turks themselves have given us an example in this respect by building their vast Hasseki hospital for Mahomedan women on a distant height well away from the crowded quarters of Stamboul. Of course, we are fully conscious of the advantage of relieving British shipping from unnecessary burdens; but we imagine that the improvement of the hospital accommodation in such insanitary towns as Constantinople and Smyrna is not an unnecessary expenditure.

THE LEPROSY FUND PRIZE ESSAYS.

We are glad to hear that no fewer than ten essays have been received in response to the questions on subjects connected with leprosy which were advertised in the columns of *THE LANCET* about a year ago. The number of questions proposed was ten, and they chiefly concern the prevalence of leprosy and its supposed causes in different parts of the world. Three of the subjects have elicited no reports, whilst one, the causes of the decline and extinction of leprosy in Britain, has produced three. The adjudicators are Sir Joseph Fayrer, Sir Guyer Hunter, and Mr. Hutchinson; and we believe that their decision will be announced very shortly. It is intended that the selected essays shall be immediately published, so far as the funds at the disposal of the committee will meet the cost. The adjudicators express themselves as highly gratified at the success which has attended this attempt at obtaining information. Many, indeed almost all, of the essays are, we understand, of great merit.

RAILWAY ACCIDENTS AND AMBULANCE ARRANGEMENTS.

THE Chelford disaster presents the almost unique spectacle of a railway accident arising from causes which did not imply neglect or mismanagement on the part of any individual. This fact, at least, in connexion with it is satisfactory. As much cannot be said with regard to some other associated circumstances. It is certainly remarkable, and not very creditable either to the prudence or the practical energy of mankind, that we have for more than half a century been in possession of a railway system, and are only now feeling our way to the formation of an ambulance department for service in emergencies like that above mentioned. And yet when the project is looked into there does not appear to be any real difficulty in the way of its realisation. Every station on every line could at no great cost of money, time, or trouble be provided with the means of coping with the sudden and urgent necessities arising out of an accident. Local practitioners might be confidently relied upon to render aid in such a case, and railway employés everywhere ought certainly to be so trained as to be of service as first aids to the injured. Such measures would avail as a temporary stopgap. A few ambulance waggons—equipped after the manner described by us in a recent issue,¹ as already illustrated on the Austrian lines of rail—could be despatched from headquarters with the breakdown train. Thus every necessity might be met promptly and effectually, life and health might be preserved, and much suffering obviated.

¹ *THE LANCET*, Nov. 24th, 1894.

As a mere commercial investment the suggested reform is not without some value, since medical aid thus early rendered might go far to prevent some of those consequences of accident which from time to time bring together passengers and railway companies in courts of law.

DIPHTHERIA IN LONDON.

FATAL diphtheria in London last week again showed decline after the serious increase of the preceding week, 34 deaths being registered, against 36, 35, and 50 in the three previous weeks. The average was exceeded by 4 only, but the admissions were 74 cases to hospital, against 80, 75, and 64 in previous weeks; and last Saturday found 517 patients still under treatment. Of the 34 deaths, 70 per cent. were in children aged from one to five years; and 4 belonged to Lambeth, 3 each to Bethnal-green and Mile-end Old Town, and 2 each to Fulham, St. Pancras, Shoreditch, Limehouse, Poplar, Newington, Camberwell, and Greenwich. In Greater London there were 13 deaths registered from diphtheria, including 9 in West Ham.

THE EPILEPTIC COLONY AT CHALFONT.

THE executive committee of the National Society for the Employment of Epileptics have just issued their first report. The aims of the society and the successful working of the colony that has been established at Chalfont in Buckinghamshire¹ have been several times referred to in the columns of *THE LANCET*. The land acquired by the society is sufficiently extensive for a settlement of several hundred epileptics, but the necessary building operations absorb a large amount of capital, and we learn with much regret that the funds in the hands of the society will be almost exhausted by the cost of erection of the first permanent building for eighteen men, leaving women and children, whose requirements are equally pressing, quite unprovided for. It is to be hoped that the next report will be able to announce a generous response on the part of the public, so that the society may be able to extend its usefulness. The movement has the cordial approval of the medical profession, as expressed by its leading members and by the medical press, and the names of the members of the executive committee and of the honorary medical staff are sufficient guarantee that subscriptions and donations entrusted to the society will be employed wisely and efficiently for the relief of the unhappy class of sufferers for whose benefit it has been instituted.

THE CALIBRE OF THE HUMAN INTESTINE.

IN communicating to the Société de Chirurgie the results of some experiments he had carried out on dogs with Murphy's anastomosis button, M. Chaput made a statement² which seems to us to open up a field for speculation, if not for inquiry. Basing his opinion on numerous measurements of the human intestines, the distinguished French surgeon informed his audience that the 27 millimetre button is far too bulky for the small gut in general, and especially for the lower end of the ileum. Of the three sizes he prefers that which is about equal to 21 millimetres in diameter; it is the smallest and adapts itself to the situation more readily than the others. Now the questions suggested by M. Chaput's remarks are these: Do American citizens, as a rule, possess more voluminous intestinal tracts than their French congeners, and, if so, how far is cookery responsible for the difference? It is, of course, notorious that French cooking is the best in the world: has this fact any bearing upon the presumably small calibre of the French bowel? Digestion being made easy, so to speak, is it the case that a partial

¹ *THE LANCET*, Nov. 17th, 1894.

² *Gazette Hebdomadaire des Sciences Médicales de Bordeaux*, No. 47, Nov. 25th, 1894.

arrest of development has been the consequence? Is there also discrepancy as regards length between the *prima vie* of the two nationalities? Savages are endowed with magnificent mouth furniture, and dental decay is sometimes said to be a product of civilisation dependent to a great extent upon knives and forks! Has the human race any reason to dread analogous deterioration as a corollary to elaborate cookery? Finally, and by way of closure to these *obiter dicta*, are dainty dishes a physiological mistake?

THE ILLNESS OF THE DUKE OF ARGYLL.

THE Duke of Argyll was seized by sudden illness while addressing a large and most enthusiastic meeting in St. Andrew's Hall, the largest hall in Glasgow, on Wednesday evening last. Some months ago the Duke's promised visit had to be postponed on account of illness, and on Wednesday night when he stepped on to the platform his appearance was that of a man who was barely convalescent. With admirable pluck, however, the Duke persisted in an endeavour to redeem his pledge, but unfortunately the task was beyond his power. The magnificent reception given him by the audience seemed to stimulate him, and his speech at first went well, but after speaking about a quarter of an hour his face became deadly pale, and he sank back unconscious into the arms of his friend Lord Kelvin. He was at once removed to an anteroom, and attended by Professor McCall Anderson, who had been on the platform, and by Drs. S. Sloan and G. R. Mather. His Grace's condition was one of most profound syncope; the pulse had almost disappeared, and difficulty was experienced in keeping up warmth in the limbs. After an hour or two of rest he was carefully removed, in the recumbent posture, to the house of Lord Kelvin, at the College, where he now lies, surrounded by friends, and in a part of the city where the requisite quiet and freedom from disturbance can be obtained. According to latest advices the Duke spent a somewhat restless night on Wednesday, but was conscious, and in other respects is reported to be progressing well. The attack of syncope was of a very profound nature, but now that he has rallied he is free from the severe epigastric pain which he had complained of before his seizure, though some abdominal tenderness remains. His illness was no doubt partly a manifestation of dyspepsia of a gouty character, though it must not be lost sight of that the Duke of Argyll is no longer a young man to whom journeys and the excitements attendant upon political affray can be considered unimportant.

"PITHECANTHROPUS": THE MISSING LINK (?).

AT the meeting of the Paris Society of Anthropology held on the 3rd inst. M. Manouvrier gave an account of the discovery by M. Eugene Dubois, surgeon in the Dutch Army at Batavia, of a cranium and femur with characters partly pithecoïd, partly anthropoid. The remains were found in the lower quaternary strata in Sumatra, and M. Dubois has published a very complete monograph upon them. The cranium of "pithecanthropus" is described as being intermediate in character between the anthropoid apes and the aboriginal Australian. It exhibits an exaggeration of the Neanderthal skull, with its enormous superciliary eminences. The cranial capacity is much greater than that of the largest gorilla, but it is less than in primitive man, and does not exceed that of advanced imbecility. A molar tooth that was found near the skull more resembles in its great size that of a monkey than of a man. The position of the occipital foramen shows that this was seated upon the vertebral column more directly than in any anthropoid ape. It most approximates to the gibbon, but the differences between the human skull and that of the

gibbon are greater than between this specimen and that of man. The femur, which was the only other part of the skeleton found (although as the site of this bone was at some distance from the cranium it may not belong to the same individual), shows that the pithecanthropus could walk erect. The femur, indeed, approximated more to the human type than the cranium. In the course of the discussion M. Duval remarked that the communication was perhaps the most important that had ever been made to the society, and thought the Netherlands Government should be asked to have casts made for presentation to the museum. He considered that the more markedly human type of the femur than of the cranium suggested that the pithecanthropus had learnt to walk in human fashion before it had developed human intelligence.

NURSING IN RURAL DISTRICTS.

MUCH has to be endured by the poor inhabitants of country villages and isolated cottages when sickness has made its appearance in the humble home. Under such circumstances the neighbours generally render willing aid to those members of the family who have to attend upon the patients, and amateur advice prompted by good intentions is abundantly forthcoming. The advantages which would follow if a better system of nursing could be introduced have long been apparent, and about five years ago some benevolent ladies of position inaugurated the Rural Nursing Association founded for the purpose of supplying this want. The council of the Queen's Jubilee Institute, recognising the usefulness of the project, affiliated the new association to their own society, and there is already a great demand for the services of their nurses, who receive their training in London and other large towns. The expense of qualifying the probationers for this charitable work is considerable, and the association's need of funds for carrying on the scheme has found expression in a letter written from St. Katherine's Royal Hospital, Regent's-park, W., and inserted in the *Times* of the 5th inst. Country practitioners will fully recognise the utility of this movement, which will directly benefit the patients and ultimately tend to improve the quality of domestic nursing.

LORD RANDOLPH CHURCHILL.

LORD RANDOLPH CHURCHILL'S condition during the last few days has been generally marked by an increase of cardiac weakness, with tendency to coma, interrupted by such occasional intervals of rallying and return to consciousness as are common in the advanced stage of general paralysis.

AFTER the dinner of the staff of St. Thomas's Hospital on the 12th inst. Dr. Ord expressed the sympathy of his colleagues with Dr. Cullingworth in the recent vexatious action unsuccessfully brought against him by a patient and presented him with a cheque for the sum which they had individually and collectively subscribed as a token of their appreciation of his conduct as a physician and regard for him as a colleague. Dr. Cullingworth, who gracefully replied, thanked those present for the unexpected expression of their kindness to him, and assured them that the knowledge of their support was a great help to him during the worries of the trial.

AN urgent appeal for public help is about to be made on behalf of St. Thomas's Hospital by the President, H.R.H. the Duke of Connaught and Strathearn.

WE understand that the Duke of Cambridge, President of the German Hospital, will take the chair at the fiftieth anniversary dinner to be held in April.

DIFFICULTIES UNDER THE INFECTIOUS DISEASE (NOTIFICATION) ACT.

I.

We are so frequently asked to advise correspondents as to difficulties which have been met with under the system of compulsory notification inaugurated by the passing of the Infectious Disease (Notification) Act, 1889, that we think it well to collect together in one set of articles the principal points as to which doubt and difficulty have arisen, and to place on record the various decisions and official interpretations which have been given with regard to them. Some of these have already been referred to at intervals in the columns of THE LANCET in answer to correspondents; others, again, have not been published in any form which is available for the purposes either of the medical practitioner or of the medical officer of health; and as regards both there will be advantage in putting them together in a form that will admit of easy reference. In doing so we would at the outset observe that, except when otherwise stated, all our comments apply to proceedings under the general Act of 1889, and not to the special Acts and codes of regulations under Provisional Orders which came into operation before 1889.

1. *Duties of the Medical Officer of Health under the Act.*

We refer here to the question whether the duties of the medical officer of health have in any way become changed in consequence of the passing of the Infectious Disease (Notification) Act of 1889. This question often arises in consequence of complaints made by local authorities to the effect that medical officers of health have failed to visit houses where infectious disease has occurred, although they have received notification to that effect. On this point the answer is perfectly clear. The Notification Act does not add to the duties which medical officers of health were required to perform before the passing of that Act. Those duties were defined under an Order of the Local Government Board, and they were not altered when the Act was passed. Whatever duty attached to a medical officer of health on receiving information as to the occurrence of infectious disease in his district antecedent to the passing of the Act still holds good; but no new duty has been assigned to him in this respect. The character of his work and the performance of any special duties remain the same; the only change that has taken place is that under the system of compulsory notification he hears of many more occurrences of infectious disease than he formerly did, and in this way duties which have always devolved upon him have undergone considerable increase. This is a point that deserves serious consideration in connexion with the revision of salaries; but when the question is asked whether a medical officer of health is bound to visit every case of infectious disease, simply because he now receives his information through the agency of a compulsory instead of a voluntary system, the answer is "Certainly not." Just as formerly, the responsibility of paying a personal visit in consequence of information received, or of not paying such a visit, devolves on him and on no one else. He alone is the judge as to the necessity or not of such a visit, and he alone will bear the responsibility of any failure to estimate aright the import of the information he receives, whether by the aid of a notification certificate or otherwise. The difference following the adoption of the system of notification is that if a certain percentage of attacks—whether 10 per cent. or 50 per cent.—calls for a personal visit the large increase in the number of cases heard of under the notification system necessarily results in this percentage being calculated on a much greater number of cases than formerly. When, therefore, local authorities ask a medical officer of health to undertake to visit every case of notified infectious disease they

make a demand upon him which is altogether beyond his duties as officially laid down. It is for the performance of those specified duties that the salary of a medical officer is paid; and if he ties himself in advance to the performance of additional ones it is to those alone who have pressed this further duty upon him that he can look for a corresponding increase in his remuneration.

Writing on this point to the chairman of the Milford urban sanitary authority on Nov. 23rd, 1889, the Local Government Board stated as follows: "The Infectious Disease (Notification) Act, 1889, where adopted, confers no new powers upon the medical officer of health, but is designed to afford him such immediate information of the outbreak of infectious disease as will enable him promptly to take such measures as are prescribed by the instructions (see Art. 18 (6) of the Order of March 8th, 1880) and authorised by the existing law (see Section 120 of the Public Health Act, 1875)."

Again, on Aug. 8th, 1890, the Local Government Board addressed a letter to the medical officer of health of South Molton to the following effect: "I am to state that the Infectious Disease (Notification) Act, 1889, does not impose fresh duties on a medical officer of health, but merely increases the sources of information upon which he acts in the discharge of his existing duty in relation to infectious disease. When that duty is determined, as in the South Molton urban sanitary district, by the Board's Order of March 8th, 1880, the medical officer of health has to take the steps indicated in Article 18 (6)—viz.: where the information points to an 'outbreak of any contagious, infectious, or epidemic disease of a dangerous character,' to 'visit the spot without delay and inquire into the causes and circumstances of such outbreak,' and to take such further action as may be necessary within his powers." [We may here state that the words quoted in this letter remain unaltered in the last issue of the Order in question.]

By some this has been interpreted to imply that each notified case of infectious disease is to be regarded as "an outbreak" of a contagious, infectious, or epidemic disease of a dangerous character, and that a visit from the medical officer of health is in consequence requisite. But the letter in no way implies that knowledge of disease under the Act as to notification calls for different action from knowledge acquired antecedently to, or otherwise than under the Act. Indeed, it is obvious that many cases of notified disease call for no visit whatever on the part of the medical officer of health. When, for example, scarlet fever is prevalent in a district, and when the medical officer of health has already visited the locality and arranged with the local medical practitioners and the sanitary inspector as to all measures of disinfection &c., it would be waste of time for him to pay a visit when each further case is reported, especially when the report comes from a medical practitioner who adds to his information that the case is well housed and isolated, and that all due precautions are being taken. The utmost that could be wanted in such a case would be a visit from the sanitary inspector with regard to the supply or use of disinfectants and the control of school attendances.

Indeed, where an effort has been made by sanitary authorities to define "an outbreak" under the Order as including all cases of infectious disease coming to the notice of a medical officer of health, the Local Government Board have declined to accept such interpretation, and they have explained that the responsibility for regarding one and another occurrence of infectious disease as constituting "an outbreak of a dangerous character" rests, not with the local authority, but with the medical officer of health. Even before the passing of the Act as to compulsory notification this attitude was adopted. Thus, writing as to this question in the case of the East Molesey urban sanitary district as far back as Feb. 22nd, 1884, the Local

Government Board stated: "With respect to the interpretation to be placed on the words 'outbreak of any contagious, infectious, or epidemic disease of a dangerous character' for the purposes (of the Section in question) I am to state that the Board are in the habit of holding the medical officer of health responsible for the judgment which he forms on the question whether any case or cases of contagious, infectious, or epidemic disease constitute an outbreak for the purposes of this Section, and have thought it undesirable to lay down minute rules in the matter."

Whilst, therefore, we should advise the medical officer of health to err on the side of paying unnecessary visits, rather than in omitting visits where there is any doubt as to their necessity, yet it should be remembered that no fresh duty as to such visits devolves on him because of the adoption of the Act as to notification, and that since he alone has to bear the responsibility for the results of any failure to pay a personal visit it is for him, and him alone, to decide whether the information he has received, whether as the result of notification or otherwise, brings the occurrence within the scope of the section of the Order which requires him to pay that visit. The section defines the object of the visit. It is that the medical officer of health shall inquire into the causes and circumstances of the occurrence with a view to advising whether, and what, measures are required to prevent the extension of the disease. It is for him to judge how far a personal visit by himself is in each case necessary to secure those ends, or how far those ends can be secured without a personal visit to the locality.

THE HOUSING OF THE POOR AT BUDAPEST.

WHAT THE INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY DID NOT SEE.

(FROM OUR SPECIAL CORRESPONDENT.)

No. II.¹

To the description of the unwholesome dwellings I was able to visit at Budapest I would now add some quotations from official documents. These are of double importance: first, they give a fuller conception of the state of things that has been allowed to prevail; and, secondly, they prove that the authorities cannot plead ignorance of these grievances. So far back as the summer of 1883 Dr. Nemenyi, member of the Budapest town council, raised the question, and a committee was appointed to inquire into the cause of the scarcity of dwellings, and an official report was issued entitled "Yelentés a Budapesti lakás ügy tárgyában, 1883." Among other significant details given in this report I find that at that time 27·37 per cent. of the habitations in Budapest had no kitchens; thus in these places cooking and washing were done in the living and sleeping room. Ten years later Dr. Gustav Thirrnig, Vice-Director of the Statistical Office, published another report on overcrowding. In this report it is stated that the number of inhabited rooms and cabinets without windows is so large that they cannot be considered as exceptions. Even stables are used as dwellings, and thirty-seven stables were found to be overcrowded by human beings. Nor were they inhabited only by stablemen, but by market gardeners, labourers, porters, and even domestic servants. Then fifteen poor labourers were discovered sleeping in the engine-house of the Royal Hungarian State Railway. In the riding school of the Franz Josef Barracks the tailor of a regiment, his family of eight, and two assistants were located. In the Soroksár-road eleven gardeners lived in wooden huts meant to be used as places for storing refuse. In the Jászberéng-road there were several tent dwellings, some containing as many as twenty labourers. In the kiln of a brick factory twenty-four men and four women lived together. In Steinbruch nineteen holes and natural caves in

the rocks were discovered not only to be inhabited but overcrowded by 182 persons. In the open fields by the outer Jászberéng-road and in the woods of Bächerwald people were sleeping. A whole family of labourers had made their home in a ditch at Bakosfalva, while a family of five persons was living in a railway waggon at Pulverturmried. Altogether I find that 2000 persons are described as living in places defined in the official statistics as "non-dwellings." On p. 890 are the following remarks: "The lodgings are in general damp, dark, and unhealthy. In some of them there are not even ten cubic metres of space per tenant. Indeed, in some tenements there are only seven or six, and here and there only two or three cubic metres of air per head. One-third of the inhabitants in these overcrowded tenements have no beds to sleep upon, and must content themselves with some other kind of resting-place or must sleep on the floor. Of those who have beds only one-tenth have beds all to themselves; the others are forced to sleep two, three, and even more than three persons in one bed."

Nor are the workers in factories, who have something like regular employment, much better off. In a pamphlet published in 1891 by Dr. Emanuel Somogyi, entitled "Die Lage der Arbeiter in Ungarn," the writer says: "That the wretchedness of the dwellings causes the economical and moral ruin of workmen's families cannot be disputed. This question has often been dwelt upon by writers on economics. Social statisticians have frequently given objective descriptions of circumstances concerning such dwellings of the working classes that would make the readers shudder, and such scenes are unveiled as would frighten even a novel writer of the naturalist school." At Budapest thirty-one factory owners have built dwellings for their workpeople, which they let out at weekly rents, and here the workers obtain cheaper lodgings. One hundred and thirty other establishments give their workpeople lodgings *gratis*, or rather include the rent in their wages. The number of workmen thus lodged was estimated at a little over 6,000. In these rent-free lodgings the most distressing overcrowding prevails. There are 120 rooms filled by people who for the most part are occupied as brick-makers. In each room three or four families are huddled together without regard to the numbers composing each family. The unmarried workmen sleep in sheds. In the distilleries sleeping-halls are erected; straw or mattresses are spread out on the floor. There is no indication that the bedding is ever washed, nor is there any ventilation provided. The official inspector of manufactories remarks in his report of the year 1887, p. 61, that "the people had an existence unworthy of men."

What is perhaps even more disheartening than all these details is the fact that so far as the overcrowding is concerned there is no improvement. On the contrary, matters are becoming worse and worse. According to the official figures there were in 1880 as many as 43,815 persons living at Budapest in dwellings where four or more persons inhabited a single room; but in 1890 the number of persons thus overcrowded is set down as 64,106. Nor is this merely due to the general increase of population. Ten years ago the proportion of persons living four and more in one room was equal to 12 per cent. of the entire population, while to-day the proportion is equal to 13·2 per cent. One improvement has, however, been accomplished: the number of cellar dwellings has decreased. Ten years ago there were 5217 underground tenements with 31,137 inhabitants, while in 1890 there were 4641 such cellar dwellings with 26,140 inhabitants.

The prevalence of cholera at Budapest in 1893 cannot have surprised the authorities. The documents from which I have made the above quotations were familiar to the administrators of the town. These terrible statistics were again brought forward at the International Congress of Hygiene and Demography by Dr. Josef Schwartz in the remarkable paper to which I have already alluded, and I was naturally anxious to see what had been done. I found that the municipality, under the stress of the cholera scare, had built on the outskirts of the town some wooden barracks which, though at first intended as cholera hospitals, are now used as cheap lodgings to relieve the overcrowding of the central portions of Budapest. I visited one of these wooden cholera isolation barracks. They consist of wooden pavilions. With the exception of the caretakers, the tenants are driven out during the daytime. The first pavilion I entered is inhabited by twenty-four women and several children. Another one has sixty occupants. The scarcity of furniture was very apparent. There are no

¹ The first part was published in THE LANCET of Jan. 5th, 1895.

chairs and no separate beds. The tenants must lie down, side by side, on bench beds which hold twelve or more persons. On these broad planks there are small, narrow mattresses and some blankets. At the foot of the bench beds there is a long board, which serves as an immovable seat. Then there is a rough wooden table, which has to be carried up to the seats. This and a little shelf above the beds are the only accommodation given. There is no sanitary convenience whatsoever within these dormitories, and it is necessary for the inmates to go out in the open. Outside there are closets, which consist simply of a board placed over a huge open cesspool. There is no pan, trough, or pail, but in each closet a partition some twenty inches high prevents those who enter from walking into the cesspool, and also serves as a sort of seat. This aperture, subdivided into closets, is some six yards long and perhaps half a yard wide, and below are the faecal matter and urine of some 400 people. There is absolutely nothing else. No water, no sand, no ashes, nothing to reduce the odour, to dilute the foul matter, and absolutely no covering to prevent the emanations reaching the outer air. The stench is, therefore, perceptible at a great distance. There are altogether six pavilions inhabited by 436 persons, each paying about a penny per day for the privilege of sleeping here. Though this charge is small, the municipality is realising a large profit on the undertaking. There are no sewers and no drains here. The slop water is simply thrown on to the bare earth, and it either sinks into the subsoil or flows into a neighbouring field where there is much stagnant water. Close by the wooden pavilions there are small cottages which have rooms let to married couples for 1-50 fl. per week. The maximum number of inhabitants in one room was two parents and six children. The room measured 3-70 by 4-21 metres and was 3 metres high. In these cottages there was a general aspect of equalor. No attempt seems to have been made to inculcate principles of hygiene; and when I was attempting to resist the nauseating effects of the open cesspool, which is only emptied three times a year, and treading slop-sodden earth in front of these wretched municipal dwellings, I could not help thinking of the model common lodging-house built in Parker-street by the London County Council. If municipal intervention cannot produce anything better than the penny plank beds provided by the Budapest municipality in its wooden cholera barracks the less of such intervention the better. The very sight of this place, especially the open cesspool and the absence of drains, is enough to convince anyone that the Budapest authorities have not yet any idea of what their duties should be in respect of the housing of the poor. How can the municipality, as the sanitary authority, call upon landlords to build sanitary dwellings, to lay proper drains, and to trap, flush, and ventilate every soil and waste-water pipe if that authority itself lodges on its own premises several hundred poor people without providing them with any of these sanitary requisites? The one great use of a municipal lodging-house or municipal tenement is that they should serve as an example to private owners and thus raise the standard all round. This is what the tenement cottages of the Huddersfield municipality, what the common lodging-houses of the Glasgow municipality, have already accomplished, and this good example is now being followed by the London County Council. The municipality of Budapest, by building and letting out as habitations wooden pavilions where there is no decent separation of beds, no chamber utensils, no semblance of comfort, no drainage, and no sanitary closets, is setting, not a good, but a very bad example.

In conclusion, a few words are necessary concerning the increase of population in Budapest and the vital statistics of that town, for these very clearly demonstrate the life-wasting results of the inefficient housing of the poor. At the beginning of this century, when there were already 55,000 inhabitants at Berlin, 300,000 at Naples, and 720,000 at Paris, Pest was but a small district with a population scarcely exceeding 2000. In 1870, shortly after the recognition of Hungarian autonomy, there were 70,000 inhabitants at Buda and 200,476 at Pest. In 1891 there were 92,465 inhabitants at Buda and 399,772 at Pest, and 14,147 soldiers. It is calculated that from 1801 to 1891 the proportion of augmentation of population has been equal per annum and per 1000 to 37-7 in London, 38-1 in Paris, 53-9 in Vienna, 70-7 in Glasgow, and 90-7 in Budapest. The birth rate at Budapest, though still very high, has decreased considerably. Towards 1870 it was about 44 or 45 per 1000, and it is now 35 or 36 per 1000. The great increase of popu-

lation is due to migration into the town rather than to the birth-rate. This has a very important bearing on the death-rate, for the people who come to Budapest in search of work are in the prime of life. They increase the total of the population, but decrease the proportion of deaths. In Hungary young persons under fifteen years constitute 37-48 per cent. of the rural population and 32-99 per cent. of the population in the towns, but at Budapest they only amount to 26-11 per cent. of the population; therefore the death-rate ought to be very low, as so small a proportion of the population are of the age when most deaths occur. Actually the deaths of children under five years are equal to 44 or 45 per cent. of the total deaths; but the insanitary conditions tell on the adults also; for, whereas the proportion of persons who die between the ages of fifteen and forty years amounts in 100 deaths to 39-92 among the rural population and to 40-47 in the towns, it is equal to 50-73 per cent. at Budapest. Nevertheless, the death-rate of Budapest has shown some signs of improvement during the last ten years, though it is difficult to say how far this is due to the greater influx of adult immigrants and to the reduction in the birth-rate. In any case the death-rate is still very high. The average for the last ten years would exceed 30 per 1000 per annum, and if, in respect to age, the population of Budapest was like that of most other towns the death-rate would be much higher still. Thus the vital statistics confirm all that has been said as to the insanitary state of the town. These unwholesome conditions, resulting in this great and preventable loss of human life, are in the main caused by the overcrowding and unsuitable dwellings. A good Building Act and a stringent law against overcrowding, with a well-organised staff of inspectors to enforce the same, are most urgently needed at Budapest. Till reforms of this description are energetically carried out, Budapest, in spite of its beautiful buildings, palaces, squares, and broad thoroughfares, will remain but a whited sepulchre.

BRITISH MEDICAL BENEVOLENT FUND.

THE annual general meeting of subscribers to the British Medical Benevolent Fund was held at 84, Brook-street, Grosvenor-square, W., the residence of the treasurer, at 4 P.M. on Thursday, Jan. 10th. The chair was taken by Dr. C. J. Hare, in the absence of the President, Sir James Paget, Bart., F.R.S. Amongst those present besides the officials were: Drs. Holman, Baines, Lowe, Brett, Milson, Eastes, and Sidney Phillips; and Messrs. Mould, Roche, Lynch, Kiallmark, Morgan, Parker, Young, and Churchill. Before proceeding to business the subscribers present desired the secretary to convey to the President an expression of their sympathy with him in the loss of Lady Paget, and regret for the sad reason of his inability to preside as usual.

The treasurer's financial statement and the report of the committee were presented by the honorary financial secretary, Dr. Samuel West, who had succeeded Dr. Sidney Phillips in the course of the year, and from them it appeared that, in the grant or immediate relief department, the receipts had been as follows: subscriptions, £1083 14s. 5d.; donations, £707 8s. 4d.—together, £1791 2s. 9d.; while £1759 had been expended in grants to 169 applicants. At the close of the year there were 104 annuitants of £20 each, absorbing £2053, and the income from investments to meet these annuities had been £1938 11s. 3d. Two legacies had been received—one of £100 from the estate of the late Mr. E. Newton, F.R.C.S., formerly a member of the committee; and one of £500 from that of the late Mr. T. Madden Stone, but the latter had been received too late for inclusion in the balance sheet. The expenses, including the collection and distribution of £3812, the printing, postage, and stationery, the collector's commission, and sundry incidental expenses, had amounted to £161 13s. 10d. The report of the committee mentioned the objects of the society and the various methods of applying the funds at disposal; and while they felt able to speak well of the annuity department they were persuaded there was room for a great deal of improvement in the contributions given for grants, which were wholly inadequate to meet the requirements of applicants; so much so that it had been necessary to use the whole of the large donations, instead of investing one-half according to the usual custom.

The committee were re-elected, and to fill the vacancies in the number Mr. Howard Marsh, Mr. John Tweedy, and Dr. Wm. Travers were elected. Messrs. Mould, Bartrum, Hodgson, John Terry, and Henry Terry were elected vice-presidents.

A feature of the fund is the selection of gentlemen as local secretaries, whose functions are to collect subscriptions in their locality, to advocate the claims of the charity generally, and to assist the committee by investigating claims upon the spot and administering the relief granted when it can be more beneficially done than by the usual method of monthly instalments through the Cheque Bank. The services of three gentlemen, Mr. G. F. Hodgson of Brighton, Mr. Bartrum of Bath, and Dr. Cooper Rose of Hampstead, all old and valued friends of the fund, have been lost by resignation, and in the two former instances successors have been appointed. The work done by all these gentlemen is worthy of the highest praise, and it is earnestly hoped that others in various parts of the kingdom will be found willing to undertake similar duties, and so add materially to the utility of the charity.

The usual votes of thanks were proffered to the chairman of committees, the treasurer, and secretaries, and the auditors, and the customary honorarium to the hon. secs. for clerical assistance was recommended. The medical press was duly thanked for the invaluable assistance invariably rendered, and the proceedings terminated with a cordial vote of thanks to the chairman.

The utility of the fund, its quiet unobtrusive help, and the excellence of its methods of applying assistance after careful investigation were eloquently insisted upon by the Chairman, Dr. Hare, in returning thanks, and he most warmly advocated the claims of the charity upon the profession.

Subscriptions and donations are urgently needed, and will be gladly received and thankfully acknowledged by any of the officers of the fund, especially the treasurer and secretaries, and particularly by the hon. financial secretary, Dr. Samuel West.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY MEETING of the Council was held on the 10th inst., the President, Mr. J. W. Hulke, F.R.S., being in the chair.

Mr. Edmund Owen was readmitted as a member of the Court of Examiners, and Mr. William Anderson and Mr. Herbert W. Page were introduced and made declarations in the terms of the oath prescribed by the Charter of 1800 on their admission as members of the Court of Examiners.

A resolution was adopted congratulating Sir John Eric Erichsen, past President of the College, on his receiving the honour of baronetcy.

The recommendation from the Committee of Management that University College, Nottingham, be added to the list of recognised places of instruction in chemistry, physics, practical chemistry, and biology was adopted.

The formulae for the alteration of Sections 4, 16, and 25 of the by-laws were approved and ordained by the Council, and the solicitor of the College was instructed to take the necessary steps for submitting the formulae to the Secretary of State for Home Affairs for sanction and ratification.

The President reported the proceedings at the half-yearly meeting of Fellows on the 4th inst., and stated that there were fifty Fellows present, including fifteen members of Council. The resolution passed at that meeting, requesting the Council to appoint a conjoint committee of members of the Council and other Fellows to consider the desirability of obtaining a new Charter, together with the details thereof, was read, but the full consideration of the resolution was deferred to a subsequent meeting.

Mr. Bryant, on behalf of himself and Sir James Paget, reported the presentation to the College, by Mr. William Hunter Baillie, of portraits of John Hunter and William Hunter, John Hunter's clock, and two volumes of autographs. The autographs contained in these volumes are of great interest and very valuable. The Council passed a resolution thanking the donor for his gift.

A letter was read from the honorary secretaries to the annual meeting of the British Medical Association, to be held in London from July 30th to Aug. 2nd, 1895, and it was

decided that a conversazione should be given by the College to the Association.

The next meeting of the Council is to be held on Feb. 7th, as the Hunterian Oration is to be delivered on the 14th of that month.

MATTEI REMEDIES IN COURT.

ON Wednesday, at the Worksope (Notts) County-court, his Honour Judge Masterman, M.A., D.C.L., had before him a number of cases which should not be without some interest to the medical profession generally.

Mrs. Blakeley, agent for Count Mattei, and who lives at what is known as the "Mattei Depot," Greenlea, Newcastle-avenue, Worksope, sought to recover payment from a number of her customers. The sums claimed were small, ranging from a few shillings to a little over £2 each, and were for "Mattei remedies" supplied. The claims had previously been, in the ordinary course, before the Registrar (Mr. J. Snow Whall), who, not feeling justified in making the desired orders, referred the whole of the cases to his Honour. There were about a dozen defendants altogether, and nearly all of them answered to their names when the cases were called on. The plaintiff, Mrs. Blakeley, did not appear in person, but was represented by a young woman named Nellie Pinder, who was examined by the judge. In reply to his Honour she said the medicine in the bottles did not come from Italy already made up, but was made up by the plaintiff at Worksope. His Honour: Is it poisonous? No, sir.—Is there no poison in it? No, sir.—Have you got the prescription? Yes, sir; it is Dr. Johnson's prescription. The witness handed up the prescription, from which his Honour read the formula Ac. 31, p. 1. which the girl said applied to Count Mattei's drugs. His Honour remarked that he could not tell from this whether there was poison in the medicine or not. But surely the law did not allow unlicensed persons to go about dispensing medicine of this sort without knowing what was in it—it was a dangerous thing if it did. The defendants—mostly women—were then called up before his Honour, and many of them made voluntary statements. One said the plaintiff promised to cure her husband in three weeks, but he had never been able to do anything since, and he had been at home fifteen weeks. Then, she added, the plaintiff sent the same medicine for all complaints. Six pills were 2s. 6d., and they were put into a bottle of water.—His Honour: I do not see that it has done much harm. All the defendants said it had done no good, and one said she was worse after she took the medicine. Still another brought up a bottle containing a transparent colourless fluid, which she said was some of the medicine, but it was "nothing but water." His Honour: You will have to pay if it is. Another brought some of the pills enclosed in the stamped wrapper, and another said there were two bottles of the medicine, "one for night and the other for morning." His Honour took possession of two bottles and said he would have the contents analysed by the Public Analyst. If they contained poison the defendants would not have to pay, but if they did not judgment must be given against them. Meanwhile, he adjourned the cases for a month. At Wednesday's court, when the cases should have again come on, it transpired that they had all been withdrawn by the plaintiff, but one of the defendants attended to claim his expenses. The application was opposed by Mr. W. A. Charles of Retford, solicitor, who now appeared for the plaintiff and gave as his grounds for opposing the application that the plaintiff brought the actions in ignorance, but upon being advised saw that she was wrong entirely. Further, she had already lost the entry fees, and she gave notice to the defendants of the discontinuance of the proceedings. He admitted that the plaintiff had no cause of action.—His Honour: Then you must pay the defendants for coming. The costs of the applicant were accordingly allowed. His Honour then stated that the report of the county analyst stated that he failed to find anything in the bottle except tap water, and he was satisfied that there was *no appreciable medicinally active ingredient present*. His Honour added that it must be remembered that it was not proved on oath before him that the bottles contained the medicine; they were simply handed to him by one of the defendants.

THE HEALTH OF THE NAVY IN 1893.

A COPY of the Statistical Report of the Health of the Navy for 1893, presented to the Lords Commissioners of the Admiralty by the Director-General of the Navy, and ordered to be printed by the House of Commons, is before us. It first of all deals with the health statistics of the total force, and this is followed by the statistics of the home station and the various foreign stations at which the different squadrons of Her Majesty's fleet are employed, and the irregular force, with an appendix of tables &c. The various sections dealing with the fleet at commands and stations abroad are illustrated by many useful small maps. The naval health reports differ from those of the army and the various medical reports of the Sanitary Commissioner with the Government of India in that the former are entirely statistical, the latter simply setting forth the results embodied in the tables, with very brief references to the assigned causes of the diseases and mortality. It follows that these naval health reports mainly consist of facts and figures which, from their nature and from the fact that they relate to a past year, are somewhat dry reading, and present little scope for commentary, criticism, or speculation. There are no papers of professional, geographical, or topographical importance or interest to be discussed.

The total force in the service afloat in 1893 was 60,120 officers and men, of whom 56.45 per cent were between the ages of fifteen and twenty-five, and 30.65 per cent. between the ages of twenty-five and thirty-five; only 1.54 per cent. were above forty-five years of age. We learn that the returns of the total force for 1893 are of a satisfactory nature. The entire number of cases of disease and injury give a ratio of 954.42 per 1000 of the mean force, which, with the exception of the preceding two years, when the ratios were slightly less, is the lowest recorded since 1856, when the publication of the present system of statistical reports commenced. Owing to the disastrous loss of the *Victoria*, when 358 deaths by drowning occurred, the death-rate is high. The number of deaths in 1893 was 679, which gives a ratio of 11.20 per 1000, an increase of 5.71 per 1000 in comparison with 1892, and of 4.69 on the average of the last six years. There is an increase in the ratio per 1000 of cases of constitutional syphilis in 1893 in comparison with that of the last six years; indeed, the report tells us that at certain stations the cases of secondary forms of the disease numerically exceed those of the primary—a matter of rare occurrence. The lowest sick-rate was on the South-East Coast of America station and the highest on the China station. The ratio per 1000 of men sick daily on the home station was 41.41; Mediterranean, 37.26; North American and West Indian, 30.66; South-East Coast of America, 27.94; Pacific, 48.38; West Coast of Africa and Cape of Good Hope, 38.58; East Indies, 47.21; China, 52.01; Australia, 36.85; and in the irregular force, 46.46. The average ratio of sickness for the total force was 41.32 per 1000, which is a decrease of 0.37 when compared with the preceding year. The ratio of invaliding for disease was 25.38 per 1000 and for injury 1.66 per 1000, the total invaliding rate for disease and injury being 27.04 per 1000.

There were 190 entries for enteric fever in 1893, of which 62 were on the home station; the remainder were mainly on the Mediterranean and North American and West Indian stations, and other stations abroad. The entire number of deaths from this disease was 37, and the invalidings 20. A solitary instance of yellow fever, which was fatal, occurs in the records of the South-East Coast of America station. Only 7 cases of small-pox are recorded.

Among the causes of inefficiency in the fleet venereal diseases occupy as usual, and seemingly as a matter of course, a very high place. There were 9321 cases; 3106 being of primary syphilis, 1593 of secondary syphilis, and 4622 of gonorrhoea and its sequelae. The number invalided for these diseases was 198, and there were 5 deaths. The loss to the nation from the number of naval seamen and from the loss of time during which they remain incapacitated for duty, to say nothing of the immediate and remote con-

sequences of this class of disease, is a matter for serious consideration. The subject is confessedly a very difficult one to deal with, and in the present state of political feeling with regard to it there does not seem to be much chance of doing so effectively. But the increasing prevalence of these diseases in the Services, and especially in the army in India, must sooner or later force itself upon the attention of our legislators.

SANITARY DISTRICTS AND REGISTRATION AREAS.

MEDICAL officers of health and others interested in the construction of health and mortality statistics have long had reason to deplore the want of uniformity and the constant overlapping between the boundaries of sanitary districts and of registration areas. There is ground for much satisfaction in the fact that the Local Government Act of 1894 has removed the main difficulty which stood in the way of more general uniformity in the boundaries of these two classes of areas, without which the construction of thoroughly trustworthy vital statistics for sanitary districts is rendered exceedingly difficult, if not impossible. For many local reasons it is obviously desirable that the subdistrict, which is the unit of registration areas, with a resident registrar, should include one or more entire civil parishes. Urban districts, however, until recently, included in many, if not in most, cases parts of civil parishes, and, therefore, registration subdistricts were in very few cases entirely situated within one sanitary district. By the operation, however, of the Local Government Act of 1894 every parish partly situated in two sanitary districts necessarily become two separate parishes. It is, therefore, now possible, as vacancies occur in the office of registrar of births and deaths for the various subdistricts, so to vary the grouping of the parishes as very materially to simplify the construction of vital statistics and to consolidate the registration arrangements for many of the towns which have hitherto suffered much inconvenience from these overlapping boundaries. To take only one town as an example: the Lancashire municipal borough of Middleton, with a population of little more than 20,000, was until recently partly situated in the three Poor-law unions of Oldham, Bury, and Prestwich; and in order to ascertain the death-rate within the borough it has been necessary to obtain, from no less than five registrars, returns relating to parts only of their respective subdistricts. The residents of this borough, moreover, have had to ascertain which of these five registrars it would be necessary for them to visit in order to register births and deaths. It may be hoped that in the near future it will be possible very considerably to simplify these arrangements. It is, however, unfortunately the fact that Poor-law guardians frequently attach more weight to the value of the patronage which they exercise in appointing the local registrars of births and deaths, in case of vacancies, than to the question of simplification of boundaries or the facilities for the construction of vital statistics. It appears that there is at present a vacancy in the office of registrar for one of the suburban subdistricts of Bolton, which includes a small part of the county borough and a few rural parishes. The Registrar-General, with a view to simplify boundaries and to carry out the spirit of the Local Government Act of 1894, proposes to add the part of this subdistrict which is within the borough to another subdistrict which is entirely within the borough, in order eventually to consolidate the whole borough in two subdistricts, instead of, as at present, small parts of the borough being situated in three outlying subdistricts. The Bolton guardians have, however, memorialised the Local Government Board to withhold their sanction to the simplification of boundaries proposed by the Registrar-General. It is, however, to be hoped and expected that the Local Government Board, which fortunately has Sir Walter Foster, M.D., for its Parliamentary Secretary, will recognise the importance of encouraging, rather than checking, the gradual process of introducing greater uniformity between sanitary districts and registration areas. It is not easy to over-estimate the importance of simplifying the construction of trustworthy mortality statistics for urban and rural sanitary districts in connexion with general health progress.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

St. Pancras Urban Sanitary District.—The general and infantile mortality in the several subdistricts in St. Pancras is well shown in the accompanying table :—

Subdistrict.	Number of deaths.	Death-rate per 1000.	Infantile mortality.
Regent's-park	761	20·3	147·5
Tottenham-court... ..	577	21·8	199·7
Gray's-inn-lane	749	26·7	236·2
Somers-town	829	24·7	213·0
Camden-town	352	24·5	170·5
Kentish-town	1895	19·7	150·4
St. Pancras	5163	21·8	176·0
London	91536	21·3	164·3

Dr. Sykes gives in his report a very interesting and concise account of an outbreak of scarlet fever which occurred in October, 1893, amongst the consumers of milk from a certain farm at Hendon. The milk in question was supplied to the customers by a milk vendor at Highgate, who obtained his milk from two sources other than the Hendon farm. It was possible, however, by a careful inquiry as to the distribution of the several supplies, to exonerate all but the Hendon milk from blame; and it appears that before Dr. Sykes's visit to the farm the county veterinary inspector had ordered the milk of five cows with sore teats to be withdrawn from the common supply, and the cows themselves to be isolated. The story which Dr. Sykes tells gives a good idea of the great difficulty and delay occasioned by having to procure a magistrate's order prior to inspecting the suspected dairies. Before being able to obtain an order to inspect the Hendon dairy Dr. Sykes called on no less than five magistrates in the district in which the dairy was situated, and he also experienced considerable delay before being able to legally enter the Highgate dairy. It seems that antecedently to the outbreak there had been at the Hendon farm one, if not two, cases of scarlet fever among those having to do with the cows, so that in this instance there was apparently illness both of cows and milkman.

Dublin Urban Sanitary District.—The corrected general death-rate of Dublin for 1893 was 28·2 per 1000, a rate which, as Sir Charles Cameron points out, is 4·88 above the mean rate for the thirty-three large towns of England and Wales for the same period. The rate is, however, slightly below that of Manchester and Preston and considerably lower than that of Liverpool. The high death-rate of Dublin is attributed by Sir Charles Cameron chiefly to the poverty and environment of a large portion of the population; and in illustration of this point he observes that one-third of the population live in single room tenements, and that in 1893 no less than 33·2 per cent. of the total deaths in Dublin occurred in public institutions frequented by the poor, a percentage considerably in excess of that observed in London and other English towns. There were eleven deaths from typhus fever in Dublin during 1893, a disease which, Sir Charles Cameron remarks, was once very prevalent in that city. Diphtheria caused in the city a very small mortality, there being but 12 deaths. On the other hand, phthisis, a disease always prevalent in Dublin, caused a death-rate of 3·9 per 1000. The deaths, too, from typhoid fever were in excess of those during any previous year, prolonged drought and heat being, Sir Charles Cameron thinks, chiefly responsible for the excess. The report upon the prevalence of typhoid fever in Dublin, which was drawn up by a committee under the auspices of the Dublin Sanitary Association, is referred to at some length by Sir Charles Cameron. After pointing out that the death-rate from typhoid fever is higher in Dublin than in any other town in the United Kingdom save Belfast, the committee consider in detail the causes instrumental in maintaining this high rate. The disease seems to prevail not only in the city of Dublin itself, but also in the suburbs, although

presumably many of those dying in the suburbs may have contracted the disease in the city. The Vartry water is practically exonerated by the committee, though they draw attention to the manner in which contamination of the water may occur in polluted cisterns. The committee, after considering all the usual methods of the spread of typhoid fever, were led to regard the contamination of the subsoil by polluted subsoil water as the chief agent in the origin and dissemination of the disease; they look, in fact, upon the polluted subsoil water as forming a suitable medium for the growth of typhoid bacilli, and they insist upon the importance of efficient subsoil drainage. In order to ascertain the levels and fluctuations of the subsoil water in several parts of the city wells were made and the levels observed. The result, in so far as the limited observations made went, was to show that the subsoil water was highest in the more elevated parts of the city and lowest in the low-lying portions near the river, this unexpected result being due, it appears, to the fact that the upper portions of the city are on clay and the lower on gravel. The fluctuations of the subsoil water in the trial wells varied from two inches and a half to three feet ten inches. It will be extremely interesting to observe the effect of the subsoil drainage, not only upon the prevalence of typhoid fever, but also upon that of phthisis. Whooping-cough and measles were added to the list of notifiable diseases in May, 1893, but in regard to the former disease Sir Charles Cameron observes that, the uselessness of its notification having been experimentally demonstrated, it has now been removed from the list.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 7072 births and 4901 deaths were registered during the week ending Jan. 12th. The annual rate of mortality in these towns, which had been 18·0 and 18·9 per 1000 in the preceding two weeks, further rose last week to 20·1. In London the rate was 19·3 per 1000, while it averaged 20·8 in the thirty-two provincial towns. The lowest rates in these towns were 14·6 in Derby, 16·8 in Bradford and in Croydon, 16·9 in Leicester, and 17·4 in Cardiff; the highest rates were 22·7 in Newcastle-upon-Tyne, 23·9 in Manchester, 24·1 in Blackburn, 25·7 in Huddersfield, and 28·9 in Liverpool. The 4091 deaths included 363 which were referred to the principal zymotic diseases, against 385 and 399 in the preceding two weeks; of these, 109 resulted from measles, 68 from whooping-cough, 66 from diphtheria, 45 from diarrhoea, 39 from "fever" (principally enteric), 33 from scarlet fever, and 3 from small-pox. No fatal case of any of these diseases occurred last week in Swansea or in Norwich; in the other towns they caused the lowest death-rates in Brighton, Leicester, Burnley, and Nottingham, and the highest rates in Manchester, Salford, Portsmouth, Wolverhampton, and Gateshead. The greatest mortality from measles occurred in Portsmouth, Derby, Halifax, Leeds, Sheffield, and Gateshead; from scarlet fever in Wolverhampton; from whooping-cough in Birkenhead, Huddersfield, and Sunderland; and from diarrhoea in Gateshead. The mortality from "fever" showed no marked excess in the other large towns. The 68 deaths from diphtheria included 34 in London, 6 in West Ham, and 3 each in Bristol, Wolverhampton, Birmingham, and Sheffield. Three fatal cases of small-pox were registered in Liverpool, but not one in London or in any other of the thirty-three great towns. There were 28 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 12th inst., against 15, 16, and 23 at the end of the preceding three weeks; 8 new cases were admitted during the week, against 1 and 8 in the preceding two weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1713, against 1931, 1890, and 1779 on the preceding three Saturdays; 130 new cases were admitted during the week, against 116 and 126 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 332 and 319 in the preceding two weeks, rose again last week to 389, but were as many as 454 below the corrected average. The causes of 82, or 2·0 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol,

Oldham, Leeds, and in seven other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Blackburn, Halifax, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22.1 and 21.8 per 1000 in the preceding two weeks, rose again to 25.5 during the week ending Jan. 12th, but exceeded by 5.4 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 10.2 in Perth and 14.2 in Leith to 28.7 in Glasgow and 31.1 in Aberdeen. The 738 deaths in these towns included 58 which were referred to measles, 19 to whooping-cough, 14 to diphtheria, 11 to diarrhoea, 6 to scarlet fever, 3 to "fever," and 2 to small-pox. In all, 113 deaths resulted from these principal zymotic diseases, against 86 and 81 in the preceding two weeks. These 113 deaths were equal to an annual rate of 3.9 per 1000, which was 2.1 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had declined from 54 to 38 in the preceding three weeks, rose again to 58 last week, of which 28 occurred in Glasgow, 19 in Aberdeen, and 5 in Edinburgh. The deaths referred to whooping-cough, which had been 18 and 9 in the preceding two weeks, rose again to 19 last week, and included 15 in Glasgow. The fatal cases of diphtheria, which had been 10, 4, and 11 in the preceding three weeks, further increased to 14 last week, of which 7 occurred in Edinburgh, 3 in Glasgow, 2 in Dundee, and 2 in Leith. The 6 deaths from scarlet fever showed a slight decline from the numbers recorded in recent weeks, and included 3 in Glasgow and 2 in Edinburgh. The 2 fatal cases of small-pox were registered in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 138 and 154 in the preceding two weeks, further rose to 215 last week, and exceeded by 58 the number in the corresponding week of last year. The causes of 50, or nearly 7 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25.4 and 28.3 per 1000 in the preceding two weeks, further rose to 31.0 during the week ending Jan. 12th, a higher rate than in any week since the end of March last. During the thirteen weeks of last quarter the death-rate in the city averaged 23.5 per 1000, against 16.6 in London and 19.6 in Edinburgh. The 208 deaths registered in Dublin during the week under notice included 19 which were referred to the principal zymotic diseases, against numbers declining from 22 to 10 in the preceding three weeks; of these, 11 resulted from small-pox, 3 from "fever," 2 from scarlet fever, 2 from whooping-cough, 1 from diarrhoea, and not one either from measles or diphtheria. These 19 deaths were equal to an annual rate of 2.8 per 1000, the zymotic death-rate during the same period being 1.7 in London and 3.8 in Edinburgh. The fatal cases of small-pox, which had been 6, 10, and 5 in the preceding three weeks, rose again to 11 last week, a higher number than in any week during the present epidemic. The deaths referred to different forms of "fever," which had been 7, 3, and 2 in the preceding three weeks, were 3 last week. The 208 deaths registered in Dublin last week included 31 of infants under one year of age and 61 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons exceeded the numbers recorded in recent weeks. Five inquest cases and 3 deaths from violence were registered; and 69, or nearly a third, of the deaths occurred in public institutions. The city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

Surgeon-Lieutenant-Colonel John Hoysted retires on retired pay. Surgeon-Captain Edward D. Bringham-Farmar, F.R.C.S. Edin., to be Surgeon-Major.

INDIA AND THE INDIAN MEDICAL SERVICES.

The following appointments are announced:—5th Regi-

ment, Madras Infantry: Surgeon-Major J. Scott, M.B., I.M.S., to the Medical Charge of the Regiment. 8th Regiment, Madras Infantry: Surgeon-Lieutenant P. C. Gabbett, I.M.S., to the Officiating Medical Charge of the Wing of the Regiment at Cuttack. 16th Regiment, Madras Infantry: Surgeon-Major E. R. DaCosta, I.M.S., to the Medical Charge of the Regiment. Surgeon-Major G. J. Kellie (Bengal), Medical Officer, 4th Lancers, to be Medical Officer of the 2nd Lancers, vice Brigade-Surgeon-Lieutenant-Colonel J. F. Sargent, who exchanges. Surgeon-Lieutenant-Colonel C. J. W. Meadows, Civil Surgeon of Murshidabad, is appointed to act as Civil Surgeon of Burdwan until further orders. Surgeon-Captain G. Jameson, Officiating Civil Surgeon of Rajshahi, is appointed to act as Civil Surgeon of Malada. Surgeon-Captain W. J. Buchanan is appointed, until further orders, to do general duty at the Presidency. Surgeon-Captain T. Grainger, Civil Surgeon of Khulna, is appointed to act as Civil Surgeon of Noakhali until further orders. Surgeon-Lieutenant Johnston has been transferred from general duty, Poona district, to general duty, Sind district. Surgeon-Colonel Robert Harvey, Inspector-General of Civil Hospitals in Bengal, has been granted eight months' leave to England. Surgeon-Colonel Raye will act as Inspector-General of Civil Hospitals in Bengal. Surgeon-Lieutenant-Colonel Patrick Murphy, M.D., retires from the Indian Medical Service.

MILITIA MEDICAL STAFF.

Surgeon-Lieutenant-Colonel T. W. S. Locke, 3rd Battalion, the Suffolk Regiment, is retired under the provisions of Paragraph 82 of the Militia Regulations 1894, with permission to retain his rank and to wear the prescribed uniform on his retirement.

VOLUNTEER CORPS.

Artillery: 1st Worcestershire and Warwickshire: John Henry Blakeney, Gent., to be Surgeon-Lieutenant. 1st Devonshire (Western Division, Royal Artillery): Lieutenant Arthur Lloyd MacLeroy is appointed Surgeon-Lieutenant. *Royal Engineers*: 2nd Cheshire (Railway): Surgeon-Major J. Atkinson to be Surgeon-Lieutenant-Colonel. *Rifle*: 3rd (Dumfries) Volunteer Battalion, the King's Own Scottish Borderers: Surgeon-Lieutenant P. M. Kerr, M.B., resigns his commission; Peter Murray Kerr, Gent., late Surgeon-Lieutenant, to be Lieutenant. 1st Surrey (South London): Surgeon-Lieutenant T. A. Daggs to be Surgeon-Captain. 2nd Volunteer Battalion, the King's (Shropshire Light Infantry): Surgeon-Captain R. de la P. Beresford to be Surgeon-Major. 2nd London: William Arthur Bond, Gent., to be Surgeon-Lieutenant.

THE LATE SURGEON ELLINGTON FRANCIS SIMEON MCKAY, R.N.

The *British Central Africa Gazette* relates the circumstances under which the late Mr. McKay, surgeon on board H.M.S. *Pioneer*, met with his death. It says: "It appears that Dr. McKay was left by H.M.S. *Pioneer* on Oct. 20th for a few days' shooting at a village near the south-west corner of Nyassa. Two days later he started with three boys to shoot elephants. After walking some hours they came to a pool of water, and seeing a lion and lioness a few yards distant Dr. McKay fired twice at the lion and wounded it. Both animals then made off for the jungle. Most of the native attendants then ran away or climbed trees, but the doctor and his Zanzibari boy, Mussa, went in search of the wounded lion. They espied the beast crouching down fifteen yards away, and the doctor fired at the lion's head. At that instant the lion sprang upon the doctor with a terrific roar, and a deadly struggle took place. Dr. McKay lost his rifle in endeavouring to keep the lion off his throat. The beast seized his left arm in its jaws, and clawed his right. Dr. McKay kicked at the lion, which threw him down and began to tear his flesh. Dr. McKay then called to Mussa, who brought the rifle, and Dr. McKay, unable to hold it up, made then made and the lion was shot. A rough stretcher was on Oct. 26th. On the same day, a little later, H.M.S. *Pioneer* returned to find him dead. He was taken to the Universities Mission Station at Likoma and buried in the cemetery there."

BRIGADE-SURGEON-LIEUTENANT-COLONEL HOOPER.

The Lieutenant-Governor of the North-West Provinces of Bengal has taken the occasion of the departure from India of this officer, who was the civil surgeon of Lucknow and is now the President of the Medical Board of the India Office,

in succession to Sir Joseph Fayrer, to place on record his appreciation of the excellent and devoted services which Brigade-Surgeon-Lieutenant-Colonel Hooper has rendered to the Government of those provinces from June, 1861, up to the present time. After eleven years' good service in the Gaol Department as Superintendent of the Central Prisons of Allahabad and Benares he was in 1874 placed in medical charge of the important station and district of Benares. In August, 1891, as a reward for long and approved service, he was transferred to the civil surgeoncy of Lucknow, where he not only earned the approval of the Government, but gained the confidence and affection of all classes of the European and native communities. "In 1881 he received the thanks of his Excellency the Viceroy and Governor-General of India, and between 1878 and 1893, on eight separate occasions, those of the Government of these provinces for the working of the hospitals and other medical institutions under his charge, and throughout a long career he has well upheld the high character of the service to which he belongs."

THE WAZIRI EXPEDITION

Some of the military columns which have taken part in sweeping the enemy's country have had a very trying time owing to the severity of the weather in Afghanistan. At Jandola, which is at an altitude of some 7600 feet, there was much snow and a severe frost, but the health of the force was reported to be good. Much greater care seems to have been taken in the present expedition than on previous occasions of campaigning in that country in providing the troops—and the native army especially, the men of which suffer from cold and exposure more than those of the British army—with plenty of warm clothing.

INCINERATORS FOR INDIAN CANTONMENTS.

The military authorities have had under consideration the extension of the incinerating system in military cantonments of stations in the hills and plains of India, with the view of preventing the pollution of the subsoil and securing surface cleanliness. The main difficulty is the cost of the necessary fuel. The object in view is a very desirable one, for many medical officers and others are of opinion that the pollution of the subsoil is not improbably at the bottom of many of the outbreaks of enteric fever in our Indian stations.

The *Pioneer Mail* states that Surgeon-Colonel Cleghorn, Inspector-General of Civil Hospitals, Punjab, is on his way out to India, and that he will presumably be offered the post of Surgeon-General and Sanitary Commissioner with the Government of India, in succession to Surgeon-Major-General Rice, who will vacate that appointment on March 29th next.

A telegram to the *Times* through Reuter's Agency says: "The stations of Naini Tal and Murree have been selected as the headquarters of the new Bengal and Punjab armies formed under the army organisation scheme which comes into operation on April 1st next."

Correspondence.

"Audi alteram partem."

THE GENERAL MEDICAL COUNCIL AND THE OBSTETRICAL SOCIETY.

To the Editors of *THE LANCET*.

SIRS,—For many years the Obstetrical Society of London has laboured in the cause of the education and registration of midwives. Meanwhile, until this object be attained by legal means the society has, at great trouble, examined women who have passed through a certain training, and given certificates to the successful candidates. The council of the society, being anxious that its certificate should not in any way offend against the Medical Acts or the ethics of the profession, when drawing it up sought the help of a solicitor intimately acquainted with the Medical Acts. The certificate does not purport to be a legal qualification, and is as much like a legal qualification as the certificates of honour granted by the medical schools to successful students in their classes, or the diploma granted to the successful brewer in a beer exhibition. The certificate, in its present form, has been used by the society for many years without complaint of any kind having been made. During the last two years the society has

received two notices from the General Medical Council pointing out to institutions granting such certificates that the certificate should be expressed in such a form as not to lead to the impression that it is a legal qualification to act as a medical practitioner; but no fault was found with the certificate of the Obstetrical Society. The society, in acknowledging the communication, mentioned the care which had been taken to draw up the certificate in accordance with the views expressed by the General Medical Council. No further communication took place between the two bodies until the society received the resolution of the General Medical Council of Dec. 3rd, 1894, and until then the Obstetrical Society was ignorant of any objection to its certificate on the part of the General Medical Council. I can hardly think that the Council can be fully aware of the full significance of its resolution, for should the society grant its certificate again the following persons will be regarded as guilty of infamous conduct by the General Medical Council—viz., all the past presidents of the society, its trustees, and other officers, most of the examiners in midwifery in the Universities of London, Oxford, and Cambridge, and the Royal Colleges of Physicians and Surgeons—in fact, all the obstetric physicians of note in London. These men, contingently branded with infamy, are well acquainted with the provisions of the Medical Acts, and many or all of them well versed in the ethics of the profession and punctilious in their observance, many of them having held high positions in the colleges and schools, and are held in honour by their professional brethren. None are better informed of the needs of the poor in their travail; none are better able to train and examine midwives; and from their learning, culture, and experience none are fitter to form correct views of what is and what is not professionally infamous. Yet these are the men who have for years been guilty of what is declared to be infamous conduct after Dec. 3rd, 1894, by the General Medical Council. Had the Council conferred with the President of the Obstetrical Society the two bodies could have easily come to an understanding on the matter (for the society has shown every desire that its certificate should be inoffensive) and avoided the ill-feeling which the resolution must inevitably cause.

I am, Sirs, yours faithfully,

JOHN WILLIAMS.

Brook-street, Grosvenor-square, W., Jan. 16th, 1895.

COLLES' LAW.

To the Editors of *THE LANCET*.

SIRS—Dr. George Ogilvie has written in *THE LANCET*¹ on Colles' law a thorough study, in which, entering again upon the discussion about the right or wrong naming of that law, he utterly attacks the Continental writers who contested Colles' titles, and me particularly. The meaning of Colles' statement appeared to Dr. Ogilvie "to be quite clear and definite"; if it were so, no debate would have probably taken place on the point, but in any case Dr. Ogilvie does not seem to have a right to say that our heresy takes its rise from the ground that "some of Colles' statements have been either misconstrued or misrepresented." And, indeed, when he confesses himself that "it may be doubted whether Colles fully realised the theoretical bearing of his law" I dare say we may be allowed to state—finding his text insufficiently clear and poorly definite—that, if Colles has forwarded a true assertion (which proves him to have been endowed with good clinical observation) he did not at all construe it. At least, nothing shows he understood so far clearly, since "not one of his cases is given to demonstrate his law," and avow the theoretical bearing of his law seems to fly very far away when he tells us how, in the case of a respectable mechanic and his wife, he noted that the servant girl received the infection from the infant, whilst the mother [who had about two years before been under his care on account of secondary venereal symptoms, of which he supposed her to have been cured] had not in a degree or in any way suffered from the disease of the child; she had not received any infection from her own child (!), yet the disease was capable of infecting the servant girl? And, however, Colles had seen cases in which the mother remained free from venereal symptoms; but I say the above case shows

¹ Is Colles' Law a Misnomer? *THE LANCET*, Dec. 1st, 1894.

² See Colles, pp. 231, 232, 233.

that he wondered as much in both cases at the mother's immunity had that one been previously free from or afflicted with syphilitic symptoms. "Of these three different ways of stating Colles' law," says Dr. Ogilvie, "that which I designate No. 1 is by far the most definite." Perhaps, had it not been slightly weakened by the case mentioned above, and, more, it is really peculiar that No. 1 precisely has not been quoted by Diday and M. Doyon, "the best advocates of Colles"; but where I can no more follow Dr. Ogilvie is when he does not hesitate to write: "I am not aware that it has been formulated in a better or more concise manner by any subsequent writer." On that point let the English readers be judges themselves:

COLLES' STATEMENT, No. 1.

I have never seen or heard of a single instance in which a syphilitic infant (although its mouth be ulcerated) suckled by its own mother had produced ulcerations of her breasts, whereas very few instances have occurred where a syphilitic infant had not infected a strange hired wet-nurse, and who had been previously in good health.

Colles, anno 1837.

BAUMÈS' STATEMENT.

Observation shows that a mother, having borne in her breast a syphilitic child who DERIVES THE INFECTION FROM THE FATHER'S SPERMIA, does not contract generally when suckling her own child the syphilitic complaint as could a strange hired wet-nurse contract it.

Baumès, anno 1840. (Précis sur les Maladies Vénériennes, Lyon, page 180.)

I am bound to state, in my turn, that, with a philologist declaring he considers the two preceding statements as being equivalent, no more discussion is henceforth to take place. And so perfect is Baumès' statement that A. Fournier, contemporaneously formulating the same idea, uses almost the same terms: "A mother never receives syphilis from her infant, even while it has contagious ulcers, when this infant hereditarily derives syphilis from its father." Besides, there is no cause to prolong the debate; certainly Colles did not catch the bearing of his observation, but he took notice of a clinical fact. He pointed it out, and therefore is worth giving his name, or half its name, to the medical law which we proposed to call Colles-Baumès' law. Moreover, let my honoured opposer be no more afraid. Use is our sovereign master; it has already consecrated the name of Colles' law, which will probably persist in spite of equity. Before concluding, let me state that I should not like to be charged with seriously looking upon a scientific contest from a national point of view. The matter which Dr. Ogilvie alluded to was a light jest that I was allowed to turn with my friends, the late Professor Diday and M. Doyon, à propos of Lyons and Paris schools' scientific rivalry; but I should not wish to be misrepresented as commonly using such ways of discussing. I hope, consequently, this debate will now come to its end, and I should not have answered Dr. Ogilvie's dissertation had not his criticisms been presented in such a paper as THE LANCET, which, being widely read, could, if not refuted, have given wrong ideas about Continental writers' erudition, ways of argumentation, and courteousness.

I am, Sirs, yours truly,

DR. A. MOREL LAVALLÉE,

Ex Chef de Clinique à l'Hôpital St. Louis.

Rue Taitbout, Paris, Dec. 25th, 1894.

"CASE OF DOUBLE POPLITEAL ANEURYSM."

To the Editors of THE LANCET.

SIRS,—I feel honoured by your reference to my case of double popliteal aneurysm published in THE LANCET of the 5th inst. Your criticisms are quite just, but the importance of the points which they raise almost demand one or two observations from me. There can be little question as to the small extent of artery obliterated in cases which have been successfully treated by my method. The recorded experience of others, as well as my own, places this point beyond dispute. As to the obliteration of the artery from the groin down to the aneurysm in the limb treated by Carte's compression, I think it right to say that it may be that the compressor was kept applied too long after consolidation had taken place, thus giving rise to coagulation in the vessel and to its final occlusion upwards from the aneurysm. But as to the comparison of my plan with that of ligature, everyone knows that in the latter the artery is generally obliterated

in at least two places—viz, at the point of the ligature and at the aneurysm—and also more or less above, below, and between these two points. Further, I hardly think that there can be any question that bad results sometimes ultimately come to the patient from this lengthened obliteration of the artery in ligature for popliteal aneurysm and consequent interference with the adequate nutrition of the limb. Such cases I have seen in which the ultimate results could not be accounted for in any other way. In other words, a patient may leave hospital with a cured popliteal aneurysm, but with the limb more or less disabled for the rest of his life. This, at all events, cannot be said of my case.

I am, Sirs, yours faithfully,

WALTER REID.

Jan. 14th, 1895.

"THE ABSENCE OF SUGAR FROM NORMAL URINE PROVED BY A NEW AND SIMPLE METHOD."

To the Editors of THE LANCET.

SIRS,—Sir George Johnson has reopened the discussion of the question regarding the existence of sugar in healthy urine. He now brings forward other evidence in support of its alleged absence, but in doing so his position remains unchanged. He seeks to disprove a positive by means of a negative. Sir George Johnson does not seem to see that as long as he remains confronted with the positive evidence afforded by fermentation and by the crystalline osazone production, which is with the greatest facility obtainable (what I have said upon this point is confirmed by German authority), all the evidence of a negative nature that he may bring forward goes for nothing.

I am, Sirs, yours faithfully,

Grosvenor-street, W., Jan. 16th, 1895.

F. W. PAVY.

THE DEBATE ON THE NATURE AND TREATMENT OF PERITONITIS AT THE OBSTETRICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—In the recorded discussion of Dr. Shaw's paper at the Obstetrical Society it seems to me that my views and teaching in this important subject have not been understood as I wish they had been, and that I am thereby submitted to an amount of misrepresentation and denunciation which is not merited. It may be, however, that I am at fault to the extent that I have not plainly expressed myself, but I can hardly put this forward, seeing that Mr. Frederick Treves in his recent address on this subject has most fully expounded my views in a very few sentences, and has given me praise for my advance, which I esteem very highly. In the necessarily abbreviated report of such a debate it is difficult to assert that the misrepresentation must arise from a misunderstanding on the part of the speakers. Thus the President says that he cannot accept my statement that peritonitis could be prevented by purging the patient. I cannot accept his statement that it is now established that peritonitis was produced by micro-organisms. Probably if we were to discuss each of those statements quietly we should find some truth in both, yet in each a large amount of error. Certainly, if I have ever said anything which has been taken to mean that peritonitis is to be prevented by purging I shall withdraw it when I revise my writings, but at present I cannot find it.

Let me briefly restate my position, which has not altered materially since 1885. Now that we have got quit of the rough mechanical and poisonous causes of peritonitis, as by the displacement of the "murderous clamp," by the ligature, and the substitution of gentle washing instead of rough sponging, the great bulk of our operations get well without even a threat of peritonitis, or whatever the condition which caused our heavy mortality may be named. Permit me here now, in intimate connexion with this part of the argument, to correct misstatements which I have lately seen in wide circulation in America, doubtless made by the incredulous for the purpose of reconciling their theories with my facts. The statements are to the effect that I always use boiled sponges and boiled water. To boil a sponge is to ruin it, and I have never made use of any effort, by boiling or otherwise, to sterilise the water I use for surgical purposes. Those who use the word *peritonitis* to signify the

* Union Médicale, March 16th, 1889, p. 412.

usual process of death, or, at least, serious progress towards it, after abdominal operations have got into a way of dividing the disease into "septic" and "non-septic," the natural outcome of which is that the former term is applied to the fatal cases and the latter to those which recover. This may be convenient, but it is neither convincing nor free from a risk of blinding us to the actual facts of the case. From my study of clinical facts and post-mortem appearances I cannot discriminate between "septic" and "non-septic" peritonitis. That there is such a thing as septic peritonitis is made clear beyond dispute by the facts of puerperal deaths, but it is in the history alone that the septic element can be revealed. I have said that the great bulk of our operations now recover without trouble or treatment of any kind. For convenience let us assume that it is 85 per cent.; the other fifteen cases give us troubles of various kinds, and some end in death. Excluding the very few cases of eccentric damage, such as secondary hæmorrhage, injury of ureter or intestine, the troublesome cases have a singular uniformity in their downward progress. Of course they are not all alike; but their resemblance is about as close as are individual instances of any ordinary disease, and their course is about as follows: the first change is one of facial expression, quite indescribable in character, but easily caught by the experienced eye, and a sign which gives warning long before danger is indicated either by pulse or temperature, guides which are by no means infallible; in fact, whilst I rigidly keep to the fashion of recording the curves of pulse and body heat I have long since abandoned reliance on them save as confirmations of what I knew before.

The next indication of downward progress is distension of the epigastrium by collection of gas in the transverse colon. If unrelieved this steadily passes into general distension. Slight occasional beef-tea vomiting comes on speedily after the disturbance is well established, and is rapidly developed into vomiting of bilious matter—at first green, then brown, then coffee-ground, and then—silence. Two points I have long ago and persistently insisted on. The first is the immediate relief of distension by purgatives, by mouth and rectum, so that I have roughly described the process as one of a race between the distension and the treatment. If the distension is not, or cannot be, overcome the patient usually dies. Usually the treatment is effective, for my nurses are drilled in the utmost vigilance in the matter of distension, and engage in its treatment at once, so that in my practice the old-fashioned death from progressive distension has become a rarity. The nurses are, of course, cautioned against the treatment in certain special cases, where it is clearly contraindicated by the nature of the operation. When such cases do succumb the post-mortem reveals the old-fashioned appearances of peritonitis. In the other cases, have I stopped peritonitis in its early stages? or have I prevented it, as suggested by Dr. Herman's denial? or have I cured it? or was there ever peritonitis present in the cases that got well? a question answered by vehement denial by a recent writer. These are very interesting subtleties for some minds—I don't trouble mine about them at all. The success of the purgative treatment of these cases, well enough defined as they must be in the practice of everyone, has now secured a world-wide recognition, and I don't care a fig about pathologico-metaphysical conundra. The second point on which I lay stress is that of time—and here I have not been so successful in securing the ear of the profession. But it is simply this, that after a completed abdominal section symptoms and conditions may occur harmlessly on the ninth day which would be fatal on the fourth. I earnestly ask those practising abdominal surgery to watch for illustrations of this curious fact, and I apologise for its further repetition.

I am, Sirs, yours truly,

LAWSON TAIT.

The Crescent, Birmingham, Jan. 14th, 1895.

PERNICIOUS ANÆMIA.

To the Editors of THE LANCET.

SIRS,—With reference to the report on Pernicious Anæmia in Fiji, by Mr. C. T. W. Hirsch, in THE LANCET of Dec. 1st, 1894, having been myself for nearly three years medical officer in the district from which he writes, I should like to make a few additional remarks. The first notes I found of pernicious anæmia in that district were in 1884 or 1885 in which attention was called to the slight influence drugs

(iron, arsenic, &c.) had on its progress. From 1890-92 it was in my experience very common amongst the East Indian immigrants. Natives and Polynesian immigrants, though working under similar conditions, but feeding more on solid root foods—e.g., yams—and being more cleanly, both in general habits and feeding, were rarely affected. The symptoms and course of the disease, as described by Mr. Hirsch, were much as I observed them, with the exception that out of 100 consecutive cases I found no retinal hæmorrhages. In about 50 cases examined post mortem, without exception I found numerous ankylostoma, and associated with them the same series of changes as described by Mr. Hirsch. Since leaving Fiji I have been pathologist to the Public Hospital, Georgetown, British Guiana, and in the course of some 1400 post-mortem examinations and numerous clinical observations have had ample opportunity of studying the changes associated with the presence of the ankylostoma. I find them in most respects identical with the so-called pernicious anæmia. The blood is thin and has little tendency to coagulate, the red corpuscles are reduced in number (frequently less than 18 per cent. of normal), whilst the hæmoglobin is only proportionately reduced; and the organs—in particular, the heart, kidneys, and the liver—are in an extreme state of fatty degeneration. In marked contrast with the latter is the highly coloured bile; there is almost invariably a deposit of hæmatoidin in the hepatic—and frequently in the renal—cells, with occasionally colourless granules, which give the iron reaction with acid ferrocyanide. The only difference noted is the absence of other than intestinal hæmorrhages. My recollections of the post-mortem examinations and cases I saw on the Rewa are so closely comparable to these that I have now, as I had then, no doubt that the disease is really ankylostomiasis. The non-observance of the ankylostomum by Mr. Hirsch in some of his cases was possibly due to the fact that ankylostoma, even before putrefaction has commenced (less than twelve hours in Fiji), cease to attach themselves to the intestines and, if a current of water is used to wash the intestines, will be washed away, or, if the fæces be wiped off with the finger, will be found in them, and not on the intestine. If either method be adopted, and the fæces or washings be not examined separately, even very numerous ankylostoma will readily escape detection.

In conclusion, the oil of male fern is not to be compared for efficacy with thymol, but even the latter, unless great care is taken in administration, will frequently be disappointing. The simple fact that thymol has been ordered and possibly given proves little. Unless care is taken to prove that considerable numbers of worms have been expelled, and by frequent examinations of the stools after the administration to show that few or no ova are found, little reliance can be placed on the results. Of course, the resemblance of the disease to pernicious anæmia is greatly in favour of a toxic action of the ankylostomum rather than the old theory of numerous minute hæmorrhages. The frequent presence of ankylostoma, even in numbers, without any obvious symptoms resulting, is not easily explicable, though in some of these cases I have found a slight illness, from which the patient apparently recovered, to serve as a starting-point for the progressive pernicious anæmia, checked only by removal of the ankylostoma.

I am, Sirs, yours truly,

C. W. DANIELS, M.B. Cantab.,

British Guiana Medical Service; late District Medical Officer, Rewa, Fiji.

British Guiana, Dec. 24th, 1894.

SEIZURE OF TINNED FOOD.

To the Editors of THE LANCET.

SIRS,—When sanitary officers are about to seize unsound food, more especially that which is tinned, I should like to point out a legal technicality which has arisen through the decision recently given in the case of *Regina v. Dennis*. This decision, it will be remembered, is the result of the appeal decided by eleven judges. The case is reported at some length in the *Justice of the Peace*, Sept. 29th. The conviction against Dennis was quashed, ten judges assenting. Mr. Justice Mathew, the only dissenting judge, in giving his opinion stated: "I do not see why, if the notice in question should be held to exonerate the seller, a notice to the same effect set up in the shop or on the barrow of the buyer should not be equally available to him as an answer to proceedings for seizure, condemnation, or punishment

under the statutes." I will now explain how this statement has bearing upon a seizure recently made in my district. On the night of Nov. 30th 392 tins containing lobster were seized in Christ-street, Poplar. At the time of seizure 15 tins were opened on the barrow, 156 tins were also opened but placed under the barrow, and the remainder were unopened on the barrow. On the barrow was exhibited a good-sized card stating, "Fresh lobster, 1½d. a tin; all bad ones changed." The 392 tins were taken next day (Dec. 1st) before Mr. Dickenson, the magistrate sitting at the Thames Police-court, who requested that all the unopened ones should be opened, and then he made the order for the contents of the whole number seized to be destroyed. The owner was summoned on Dec. 7th for the exposure of the lobster. The defendant's solicitor pleaded that the contents of the tins under the barrow were not exposed for sale, but were placed there in order to be destroyed, and that the contents of the only tins exposed for sale were those of the fifteen opened ones on the barrow; and he argued that so far as the unopened tins on the barrow were concerned the defendant covered himself by exhibiting the notice, "All bad ones changed." When I was giving my evidence I was asked, "Did I see these fifteen tins apart from all the other opened tins?" My answer was in the negative, for when the sanitary inspector sent for me to go to Poplar Police-station the fifteen opened tins were mixed with the other opened ones taken from under the barrow; but I explained that these fifteen opened tins could not have been good because there was not one good tin among the whole number seized. The defendant was fined £5 and 30s. costs. Now, Sirs, as I was unable to pick out the fifteen tins, I feel certain that a conviction would not have been obtained if the whole number of opened tins had not been bad. This shows from the recent decision, in order to obtain a conviction for exposure, the importance of keeping separate at the time of seizure of tinned food any tins exposed on a barrow or stall. This may seem a trivial point to write about, but I have had some little experience in seizing tinned food in the streets, and I may say the duty is not a pleasant one, especially in a crowded market street late at night, when one is liable to be hustled and the tins mixed.

I am, Sirs, your obedient servant,

FREDK WM ALEXANDER,

Medical Officer of Health, Poplar and Bromley.

Wellington-road, Bromley-by-Bow.

ISOLATION OF CASES OF OVARIOTOMY.

To the Editors of THE LANCET.

SIRS,—In your account of the proceedings of the last meeting of the Royal Medical and Chirurgical Society I am reported to have said that I "did not see great objections to ovarian cases being put in general wards." May I ask you kindly to allow me space to explain that I said it seemed to me most undesirable to put these cases with other patients until convalescence was so far advanced that a satisfactory termination of the case was assured? Septic peritonitis is the great danger of these cases, and septicæmia is more apt to occur when a patient is put in a ward beside others suffering from various diseases than when she has a room for her own use, and the risk of infection is especially increased in drainage cases. It should be remembered that with a wounded peritoneum mischief of an irreparable nature may be done in a moment, and that a degree of septic infection which would only cause a temporary rise of temperature and irritation of tissue, with perhaps an abscess formation, in a superficial wound such as that of an amputation of the breast might kill with great rapidity if it came into contact with the peritoneum. Many cases of ovariectomy require constant attention from the nurses for three or four days, and sometimes much longer, after the operation, although they may eventually make complete recoveries. It cannot be good for the patient herself to lie in a general ward when she is very ill, or for other patients to see her in that condition; and as it is quite impossible to tell beforehand whether a patient will require drainage of the peritoneum, and whether she will make an easy or a difficult convalescence, it seems to me that the plan of isolating these cases has all the advantages that can be claimed for their treatment in a general ward and many recommendations besides. Ovariectomy could hardly have been brought to its present state of excellence without isolation of the patients, and this excellence is not likely to be maintained and increased if less care and

attention are devoted to the patients than formerly. I am strongly of opinion that it will be found to conduce to the safety of patients, after abdominal section has been performed, to treat them in private wards as long as they are acutely ill.—I am, Sirs, your obedient servant,

Portman-street, Jan. 12th, 1895.

JOHN D. MALCOLM.

"THE BARIUM WATERS OF LLANGAM-MARCH AND THE THERAPEUTICS OF BARIUM SALTS."

To the Editors of THE LANCET.

SIRS,—Dr. Cruise's letter in THE LANCET of the 12th inst. on the use of barium salts appears to me especially valuable as indicating the smallness of the dose (one-sixth of a grain of the iodide three times a day) required to produce "remarkably good results," his experience extending over a period of thirty years. Whether the iodide is a more active or more desirable form for administration than the chloride I will not now discuss; but from my personal knowledge of the favourable results experienced from the use of the Llangam-march water I should prefer to prescribe it in the form in which it exists in that spring. It is to be hoped that neither medical men nor their patients in their anxiety to try a new remedy will be led into the error of adopting any but the most moderate doses, for I feel convinced that experience will demonstrate that all the beneficial results are to be obtained from doses considerably less than a grain of the barium salt—that is to say, in tumbler doses of the Llangammarch waters. Judging from the similarity to arsenic in some of its effects as an alterative, together with what I have learnt of the remarkable benefit that has accrued from the use of the Llangammarch waters in some cases of *anæmia*, some of which are mentioned by Dr. Bezly Thorne in THE LANCET of Dec. 1st, 1894, I am strongly impressed with the probability of its proving beneficial in cases of pernicious *anæmia*. It certainly merits a trial in that direction. Another class of cases in which I have known it to prove serviceable is in chronic gastric catarrh and in flatulent dyspepsia.—I am, Sirs, yours faithfully,

FREDERICK GEORGE, M.D.

Albemarle-street, W., Jan. 15th, 1895.

CORONERS' INQUESTS.

To the Editors of THE LANCET.

SIRS,—The question whether, in these days of improved medical science and the daily paper, it is necessary to maintain the obligation upon coroners and their juries to view dead bodies upon which inquisitions have to be taken is one that is constantly cropping up, and every session of Parliament sees a Bill introduced by a different group of members, having for its object the relief either of the coroner or the jury, or both, from the duty, or leaving it to the coroner to determine whether the jury shall view or not in any particular case. Attention having been drawn to the subject by a resolution of the council of the Coroners' Society, expressing the opinion of the council "that no alteration in the existing law is required or is desirable, and, further, that an attempt to do away by law with the view of the body by the coroner and jury would be prejudicial to public interest and policy and detrimental to public confidence in the court," which appeared in THE LANCET of Nov. 17th, 1894, I venture as a provincial coroner to submit that there are two sides to this as to most other questions, and that even among coroners there is a difference of opinion on the subject. May I beg space to discuss it in some detail? Those coroners who support the maintenance of the *status quo* assert that the whole of the coroner's jurisdiction is based on the existence of a dead body, that though a person be lost the coroner has no function to inquire after him unless and until his dead body is found, and that the inquisition can only be taken *super visum corporis*, and that the dead body itself is a material part of the evidence upon which the jury must ground their verdict; that if coroners lose the right to view the body they will weaken their right to take possession of and deal with it as they think necessary by way of post-mortem examination or otherwise, so as to ascertain the true cause of death; that the view is an ancient and desirable part of the proceedings of an inquest, and ought not to be lightly given up.

Those coroners, on the other hand, who consider that a

change is desirable argue that, however necessary it may have been in ruder ages for the body to be viewed, when deaths by violence or exposure were more common than happily they are to-day, and medical skill and science were not so readily procurable as evidence to lay before the jury, still, in these days of glaring publicity by means of the daily papers and the ubiquitous pressman, the view answers no useful purpose; that the view may be of any other use than to demonstrate the existence of a dead body, the body must be examined by the jury, back, front, and sides, involving an indecent exposure of it that is most unbecoming, and in all cases of natural death the proceeding gives no information to the jury whatever. If death has been due to violence, as by accident in machinery or running over by a locomotive, and the body is much mangled, a medical man or a butcher may view it without abhorrence, but the ordinary jurymen can learn nothing from the spectacle. Neither can he tell whether a person with a cut throat has been murdered or has committed suicide; he has to rely on medical evidence as to the extent and direction of the wounds to enable him to form a judgment. So on the question of establishing identity. The view may have been useful in early days when people did not move far from home in a general way and the whole of the inhabitants of the locality above twelve years of age were required to attend the inquest. But now how are things changed. A jury is summoned to inquire into the death of a miser in a county hospital. He has been brought in from a colliery miles away; the jury live within a radius of half a mile from the hospital. How can the view help them? It would seem reasonable, if a man has been killed by machinery, a fly wheel, or a revolving shaft, or what not, that the jury should view the scene of the accident, for then they could judge of the degree of responsibility of the owner of the premises, but what can they learn from the body except its existence? And still stronger is the argument against the view when death is due to natural causes and a post-mortem examination has to be made to ascertain the precise cause. Of course, the conditions under which inquests are held in different parts of the country may, and probably do, affect the opinion of coroners. In London, if I am not misinformed, the coroners hold their inquests in a suitably equipped court, and the bodies lie in a mortuary conveniently near to the court, so that they may be viewed by both coroner and jury without trouble or loss of time. In Liverpool and Birmingham, and possibly other large towns, the coroner has a central court where the jury assemble and are taken thence in a coach from house to house where the bodies lie, in order that they may see them before hearing the verbal evidence. Imagine what this must mean in loss of time to a dozen or more jurymen, who, if they receive any remuneration at all, receive only an honorarium varying from 8*d.* to 1*s.*

In most smaller towns no coroner's court is provided, and the mortuary accommodation is usually of a very limited description. Consequently, in order that the view may be performed, inquests are held in the public-house nearest to the house where the body is lying, and the jury and coroner have to parade in a body through the streets, followed by a crowd of curious children, or, maybe, in a pouring rain or driving snowstorm, oftentimes into a tiny cottage, up a dark and crooked staircase, to a small back room lighted with a tallow candle or small paraffin lamp, and with a floor which it is by no means certain will bear the weight of the party; then back, wet and ill-tempered, to the public-house, where the witnesses will be found either taking advantage of the hospitality of the house or huddled together on the stairhead outside the club-room, because there is no ante-room available wherein they can sit. But in the country districts how are things managed? I prefer that some county coroner should, if he will, describe them. Country jurymen, I believe, usually have some remuneration paid to them for their time and service, but how far it exceeds an honorarium or is worth carrying away as cash from the inn where the inquest is held I cannot say. My position, therefore, is: relieve the jury from the obligation to view, except in cases where the coroner feels that they can gather some useful information from it, or where, after hearing the evidence, they themselves express a desire to see the body. A simple enactment, "It shall not henceforth be compulsory upon the jury except, &c.," is sufficient. But because I believe that the general public attach great value to the duty of the coroner, and would feel greater security and satisfaction if he remained under the obligation to view,

I submit that this obligation should be retained. The coroner is more or less adequately paid for his services, and must be content to take the disagreeables of the office with its sweets—he need not take either unless he likes; but the jury are pressed into the service whether they will or not, and usually without anything but a nominal acknowledgment for their time, and therefore ought not to be required to undergo a disagreeable and practically useless ordeal, but for which they might be summoned to a suitable court, where the inquiry would be conducted with some show of decency and dignity instead of under such conditions as I do not care to describe in further detail. By such a course no possible advantage, so far as I can see, would be surrendered by the coroner, while a duty which at no time is a particularly pleasant one would be rendered less irksome to a multitude of people, and the office, therefore, would become more popular and secure.

I am, Sirs, yours faithfully,

CHAS. L. ROTHERA.

Nottingham.

*** There are good arguments for and against the abolition of the procedure. It is clear that if the jury view the body, such view should take place under the most favourable circumstances; say through a window, and certainly not under conditions likely to be of personal danger to them. It is possible that the view may be required for purposes of identification, and the dispensing with the ceremony might complicate very much the position, for example, of the surgeon making the necropsy. A sudden death attended with no suspicious circumstances might, upon post-mortem examination, be found to be due to poisoning, and a charge of murder ensue. If the body has been viewed by the jury no difficulty can arise, as the necropsy has been performed upon a corpse which has been seen by the jury, and has been identified on sworn evidence before them to be the particular body. In the absence of the ceremony of viewing, the examining surgeon might be placed in a serious difficulty. But proofs of identity by trustworthy witnesses are generally forthcoming, and no one can desire to thrust upon the jurymen without adequate motive, and with possible risk to his health, the presence of death in a repulsive form.—ED. L.

SEA-SICKNESS.

To the Editors of THE LANCET.

SIRS—May I enter a slight protest against the universally enthusiastic reports which have hitherto appeared on the action of chlorobrom in sea-sickness? After some months' trial of it I found the results quite as unsatisfactory as those from any of the other so-called specifics. Its action is certainly too depressant for use in very severe cases, especially in debilitated subjects, such as are sometimes met with returning from the East. I have found acetate of morphia give very fair results in most cases, administered in minute doses frequently repeated, care being taken that only the stimulant effect is produced. Minim or two-minim doses of dilute hydrocyanic acid may be added with advantage. Of more importance, however, I think, are other palliative measures, such as the removal of a patient to a well-ventilated midship cabin, with the berth running fore and aft, and the removal of any articles which can swing or roll about with the motion of the vessel. In connexion with the latter precaution it is interesting to note that since fixed electric lamps have superseded the old-fashioned swinging oil-lamps in ships' saloons much less discomfort is felt by indifferent sailors and fewer cases of sudden retreat from the table occur.

I am, Sirs, yours faithfully,

Dec. 12th, 1894.

A. M. C.

THE ABUSE OF HOSPITALS, DISPENSARIES, AND CLUBS.

To the Editors of THE LANCET.

SIRS—With the abuse of hospitals, dispensaries, and clubs existing, is it not time that a table should be drawn up by some authoritative body and a minimum fee fixed? The struggle for existence is so severe that anything which takes

away many hundred pounds from the younger members of our profession should be closely criticised. I know one public charity where it is gravely contended and practised that the families of policemen and fire brigade men should be attended free. I venture to suggest two points. Firstly, that all applicants for hospital, dispensary, or club treatment should state the total income of their families, which should be entered on the usual card or letter. In this way we should be able to get at the income of those using our charities, if nothing else. If applicants make false statements would it not be possible to prosecute (one or two for an example) for obtaining charity and medical treatment under false pretences? If charities refused to carry out these rules it should be a bar to any participation in hospital funds &c. (Sunday, Saturday, &c.). If medical men should so far forget themselves as to support such a charity, ought they not to be blackballed? Secondly, the following table is suggested for the purpose of discussion: 1. To be eligible to all free charities—(a) single applicants earning less than 18s. a week; (b) married applicants earning less than 25s. a week. 2. Applicants with family earning less than 30s. a week to pay up to 3d. a week in any club or public dispensary. 3. Applicants with family earning less than 33s. a week to pay up to 6d. a week in any club or public dispensary. 4. Applicants with a family earning less than 36s. a week to pay up to 9d. a week in any club or public dispensary. 5. Applicants with a family earning less than 40s. a week to pay up to 1s. a week in any club or public dispensary, and so on.

A public dispensary in each district, especially towns, to which all medical men residing in the district should be eligible, would be beneficial both to the public and the younger members of the profession. One medical man might be appointed to the dispensary for each ward of the district. The public dispensary to be controlled by an equal number of medical men and members of the dispensary &c., the chairman to be a medical man. Details such as number of wards in district and election of medical men and committee are minor details. I am, Sirs, yours faithfully,

Jan. 14th, 1895.

PHYSICIAN C.

To the Editors of THE LANCET.

SIRS,—I consider that the letter appearing in your issue of last week does not appear too soon, and I hope not too late, to put intending candidates for the Pendleton Dispensary in Manchester upon their guard. There is an advertisement in one of the daily papers to-day (Tuesday), which, of course, gives no information to candidates of the conditions of the appointments. The gentlemen who have resigned have for the most part been engaged upon the staff during several years, have acquired large private practices, and are well known, who will oppose the dispensary to the utmost degree on its own lines, and who have been positively driven to this course; by their action at various times in the interests of the profession at large, and as a protest against unprincipled interference on the part of lay committee men. I am not, nor ever have been, in practice where these medical men have resigned, so that I can write with more freedom. I am reluctant to trespass upon your space too far at present, for the indictment against the provident dispensary system is a long one, but wish to point out to those who desire to try their fortune the following points: (1) to insist upon a guaranteed minimum salary, otherwise they may be told at the end of a quarter that they are entitled to half the subscriptions of a dozen members; (2) not to bind themselves not to practise in the district; and (3) to see that the rules are strictly carried out in their favour.

I am, Sirs, yours truly,

M.D.

Jan. 15th, 1895.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Twenty-fifth Anniversary of Hospital Sunday.

ON Jan. 8th, 1871, Hospital Sunday was first observed in Liverpool, after a somewhat perilous launch, in which its promoters were much assisted by THE LANCET, which had for some time previously warmly advocated the cause as worthy of adoption throughout the length and breadth of the kingdom. Those who urged its adoption gave £4000 as a probable result, instead of the paltry sum (less than £1000) which

a few favoured medical charities had previously received, while other institutions had received nothing at all from church or chapel collections. The total of the first Hospital Sunday collections reached £4765, the total for 1872 being £6923; this upward tendency was maintained in the two following years, which produced £8124 and £8848 respectively. Since then the tide of charity has ebbed and flowed. The average amount of the Sunday collections for the twenty-four years which have passed since Hospital Sunday was first established in Liverpool has been £6979, a sum which has fully realised the wishes of those who promoted this means of raising money for the local medical charities. With the aid of Hospital Saturday a sum of nearly a quarter of a million has been raised in twenty-four years. Last Sunday was the twenty-fifth anniversary, or "silver wedding," of Hospital Sunday. A bitter north-east wind and a heavy mantle of snow, though appropriate in one sense to a silver wedding, was hardly conducive to large congregations. Still, the date being always the same—the second Sunday of the New Year—there have been inclement Sundays before, and when such a magnificent average can be shown one feels the full significance of the old saying, "Leave well alone." Perhaps, however, the change of date from January to February may be practicable and profitable.

New Medical Magistrates.

Dr. William Carter and Mr. Richard Williams have been placed upon the Commission of the Peace for this city. Both of these gentlemen are well known and are highly respected by their professional brethren and by the public generally.

Jan. 13th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Wholesale Poisoning.

WHAT is now known as the "Wylde Green poisoning mystery," to which reference was made in the columns of THE LANCET last week, has been the subject of much discussion. The actual cause does not even yet appear to be clear, in spite of the light brought to bear upon it. It seems that over 100 people partook of some soup prepared by the landlady of a public house. Nearly all these persons were subsequently seized with sickness, diarrhoea, and collapse in varying degrees of intensity. One woman aged forty-seven died. With regard to her case it is but fair to state that she had been an invalid for some length of time, but that her immediate end was brought about by this particular soup. At the inquest held upon her body it was shown that the meat from which the soup was made was what is known in the trade as "stickings," and that along with a number of other pieces of the same kind it was kept at the butcher's in a tub of brine. The composition of this was stated, and it was proved that other pieces from the same tub were sold without injury following. Dr. Hill, the borough analyst, had examined the soup, but found no poison. His opinion was that the death and illness resulted from septic charge in the brine. The inquiry was adjourned for a post-mortem examination to be made, the coroner adding that an expert should be sent to assist the medical man in charge.

Another Form of Poisoning.

The coroner for West Bromwich on the 7th inst. held an inquest on a boy five years of age who had been eating tobacco. The medical man who made the necropsy attributed his death to this poison, and a verdict was given accordingly. There is no accounting for perversion of tastes, but in an instance of this kind it can hardly be thought that a small boy would eat tobacco from choice—certainly not if anything more acceptable was at hand.

Lectures on Diphtheria.

The health committee having instituted a series of lectures on the Laws of Health, the subject of Diphtheria was discussed by Dr. Line on the 11th inst., Alderman Cook, the chairman of the committee, presiding. Mr. Cook contrasted the death-rate of Birmingham with other towns from this cause and dwelt upon the precautions necessary to avoid this disease, such as cleanliness, isolation, ventilation, and dry houses. Dr. Line's address was listened to with much interest and attention.

The Weather, Sickness, and Work.

In spite of the severe weather in various forms of intensity

thick fogs, acute winds, and deep snow, there is a prevailing impression that the health of the district is unusually good. From conversations with several medical men in different districts it has been gathered that they have never had so little to do at this time of the year. No doubt some of this may be due to the more active competition in the profession, and the readiness with which work is seized by newcomers. Apart from this unfortunate cause the complaint is one of general slackness and inactivity.

Jan. 16th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Medical Education of Women in Edinburgh.

THE annual report of the Scottish Association for the Medical Education of Women has been published. It is noted with satisfaction that for the first time since the formation of the association income and expenditure have nearly balanced each other. There has been a continued steady increase in the number of students attending the college of the association in Chambers-street. Reference is also made to the fact that by reasonably pushing the claims of the association their college has been recognised by the University of Edinburgh as a medical school whose course of instruction should qualify for graduation in medicine, and the court of the association hopes that this will increase the interest taken in the association and the work it is doing, for it increases the responsibility for having the college fully equipped. The court further draws attention to the fact that the University retains the right to withdraw the leave granted to extra-mural teachers of providing a complete course of instruction for graduation in medicine for women. If the intra-mural classes be opened to women they will be put on the same footing as the male students, and will require to take at least one-half of their medical course within the walls of the University. A school for female students only, affiliated to the University, would put the thorough medical education of women on a permanent basis, do away with the necessity of disturbing university arrangements for the instruction of male students, and be a fitting complement to the other educational facilities provided in Edinburgh. The report makes an appeal for endowment, which is considered to be an essential to the successful application for affiliation.

Annual Report of Queensberry House, Edinburgh.

As has been noted on previous occasions in THE LANCET, this institution is a home for inebriates, and also for aged and infirm persons who can pay a small sum for board or are paid for by their friends or relatives. The report shows that the daily average number of inmates was 271. Dr. William Russell, the visiting physician to the institution, says in his report that the past year was characterised by an exceptionally low rate of sickness. Twenty-three deaths had occurred during the year, and of these 60 per cent. were of persons over seventy years of age, while only four were not above sixty years; eight deaths occurred between seventy and eighty years, four between eighty and ninety, and two were in persons of ninety years or more. Dr. Russell attributes the prolongation of life in a large measure to the physical comforts with which the inmates are surrounded and the simplicity of their diet. In regard to the deaths it is noted that in nearly every instance death was due, not to the exhaustion and debility of old age, but to a distinct lesion of some special organ.

Small-pox in Edinburgh and Leith.

Ten fresh cases of small-pox were reported in Edinburgh and two in Leith during last week; in this period there were two fatal cases of small-pox in Edinburgh.

Royal Lunatic Asylum, Glasgow.

During the past year 149 patients were admitted to this asylum; 113 were discharged (47 of these being recoveries) and 31 died. The year had begun with 490 resident patients, and it closed with 495, the private patients numbering 374, and those chargeable to parish authorities 121. Sundry changes have been made recently in the asylum, all contributing to its efficiency. Among these may be mentioned arrangements for a more copious water-supply (to ensure the safety of the building in possible emergency) and the fitting

of a smoke-consuming apparatus to the boiler furnaces—the latter a step which the other hospitals of the city should take without delay, were it only for the sake of example to the smoke producers.

Glasgow Convalescent Home.

This home, now in its thirty-first year of existence, has sheltered no fewer than 1747 patients, whose average stay had been sixteen days and one-seventh, at a cost of £1 6s. 1½d. per patient. Unfortunately, like so many other medical charities, its income fell short of its expenditure by about £300.

Suffocation by Gas.

Last week an entire family, consisting of husband, wife, and five children, living in a sunk flat in one of the poorer districts of Glasgow, were suffocated by gas which leaked from a broken gas-main in the roadway. The breaking of the pipe is attributed to the recent severe frost. Six months ago another family, also living in a poor part of the city, and numbering five members, were similarly killed, the gas in this case coming from the open end of an abandoned pipe. Both accidents point to a certain degree of carelessness in workmanship, and emphasise the terrible risks run by those who live in such half-underground hovels (which should not be allowed to exist in our midst), while the importance of even a little ventilation, especially in crowded apartments, is abundantly demonstrated.

The Illness of the Duke of Argyll.

The fainting fit into which the Duke of Argyll fell when addressing a political meeting on Wednesday evening last produced a profound sensation in Glasgow, which rapidly spread over the United Kingdom. His Grace soon rallied, and all alarming symptoms had subsided by Thursday morning.

Jan. 15th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Outbreak of Small-pox in Dublin.

DURING the week ending the 12th inst. 88 cases of small-pox were admitted to hospital, being 17 in excess of the admissions for the previous week. Eleven deaths were recorded from small-pox, and 194 remained under treatment on the 12th inst., being 24 over the number in hospital at the close of the preceding week. Since the appearance of the disease in July last 84 deaths have occurred, all of which, with one exception, took place in hospital.

Accident to Mr. E. S. Bricknell of Queenstown.

As Mr. Bricknell was walking last week in Queenstown he slipped and fell on the footpath, which was very slippery from the frost, and sustained a fracture of the right arm a little above the elbow. He is progressing satisfactorily.

An Unfounded Rumour.

It was rumoured last week that the President of the Royal College of Surgeons in Ireland and a physician in Dublin had been offered the honour of knighthood, but the statement was without foundation.

The Position in Cork.

The attitude of the medical men in Cork remains exactly the same, and as this attitude has been unanimously adopted it must result in victory. The medical men so obviously demand only what is fair—viz., that they should be paid by those who can afford to pay them—that no other issue was to be expected.

Proposed Presentation to Dr. H. St. J. Brooks.

A number of friends of Dr. H. St. J. Brooks have decided to make a presentation to him on the occasion of his leaving this country for Australia. A committee has been formed, consisting of the present staff of demonstrators in the School of Anatomy, Trinity College, Dublin, to communicate with those past students who have had the benefit of his teaching and with those who have known him during the thirteen years that he has been associated with the school as Chief Demonstrator and University Anatomist. Subscriptions to the presentation will be received by either of the following gentlemen (addressed Medical School, Trinity College, Dublin): Dr. A. F. Dixon, Dr. H. C. Drury, Dr. E. H. Taylor, Dr. T. E. Gordon, and Dr. G. Jameson Johnston.

High Death-rate of Children in Belfast.

At an inquest recently held in Belfast, where a child died from being overlain in bed, the coroner animadverted on the high death-rate of children in that city. This was the fourth inquest on children he had already held in the present month, and he was surprised at the parents not taking even the trouble to get medical relief. The jury in their verdict said there was neglect on the part of the parents. The coroner administered a severe caution to the parents. He said Belfast was no exception to the rule in the matter of the high death-rate of children, for in Liverpool, Leeds, Manchester, and other large towns the death-rate was also very large. On examination he had found that a large number of those deaths occurred on either Saturday night or Sunday morning, and that it was to be attributed to persons getting their wages on Saturdays and becoming drunk, and so the children were overlain in bed. He hoped that that case would be a warning to other parents.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Sero-Therapy.

It frequently happens that a discovery ridiculed at the time is subsequently applied practically by other persons and the credit transferred from the original discoverer to these latter individuals. In France sero-therapy is believed to date from the experiments of MM. Richet and Héricourt, already reported by me in the columns of THE LANCET. These savants, relying on the immunity of the dog to tuberculosis, employed the blood of this animal as a prophylactic. It was only in 1890 that they made use of dogs previously immunised artificially. The earliest communications of MM. Behring and Kitasato are dated 1890. There now comes forward M. Babès of Bucharest, who, through his friend Professor Cornil,¹ claims precedence in the discovery, alleging that his researches, conducted in collaboration with M. Lepp, were published in the *Annales de l'Institut Pasteur* in July, 1889, and that, further, they applied the method to human beings in the following year. M. Babès therefore claims the paternity of the following laws, wrongly denominated Behring's laws: 1. Immunity against an infectious disease may be conferred on animals by injections of the blood of another animal already strongly protected (artificially) against that disease. 2. The application of that method prevents the development of the disease in animals previously inoculated with the virus of that disease. Honour to whom honour is due; but suffering humanity will not be parsimonious in its thanks to both early and late workers in a field that bids fair to revolutionise the healing art and render the latter years of the present century famous in the annals of medicine.

A New Sign of Diabetes and Albuminuria.

M. Garel of Lyon² claims to have discovered a hitherto unrecorded physical sign which is almost pathognomonic of either diabetes or albuminuria. He states that many patients complain of a slight irritation of the throat—some difficulty of deglutition, a sensation of swelling, and constriction of the fauces. The soft palate, its pillars, and the posterior wall of the pharynx are found to be red and swollen, and frequently covered with a more or less viscid layer of mucus. In the majority of such cases examination of the urine reveals the presence of either glucose or albumen. Most of these patients present only quite insignificant general symptoms, so that M. Garel's discovery, if it be confirmed, is of considerable value. Of twenty-one individuals affected with this particular form of pharyngitis, ten had diabetes and eleven albuminuria, and in three of the cases sugar and albumen alternated in the urine. I would, however, ask if it be not the wiser plan to analyse, as a matter of routine, the urine of every new patient, more especially when middle age has been reached? In my own practice I make it a rule to do so, and I have thus avoided many a *fausse piste*.

Blood Changes in Myxœdema.

M. Lebreton³ has recently studied the urine and blood of a myxœdematous child both before and after treatment with

thyroid gland. In forty days the treatment had determined considerable improvement in the physical and mental condition of the child. The only modification in the urine noted during treatment was slight and transient albuminuria. As regards the blood before treatment it contained 1,750,000 red and 4500 white corpuscles, as against 2,450,000 and 9600 after treatment, the hæmoglobin being also increased in the proportion of 68 to 65. Before treatment the average diameter of the red discs was 0.1 mm, that of some giant elements reaching 0.57 mm. Treatment reduced the diameter of the coloured corpuscles to 0.57 mm. In preparations dyed with hæmatoxylic eosine there were seen some red discs provided with nuclei, which disappeared after treatment. The proportion of mono-nucleated to poly-nucleated leucocytes was raised by treatment from 15 to 25 per cent. to 30 and even 40 per cent., the latter proportion exceeding the normal. A considerable number of small lymphocytes present before had almost disappeared after treatment. Mucin, said to have been discovered by certain authorities in the blood of these patients, was conspicuous by its absence both before and after treatment. It would thus appear that myxœdematous blood differs from the normal fluid in the persistence of the foetal hæmopoietic process, characterised by the presence in it of nucleated corpuscles and by the large diameter of the red elements. M. Lebreton's researches also show that the cure of myxœdema is synchronous with a leucocytic process of a particular kind, the increase in the white corpuscles involving exclusively the large mono-nucleated variety.

Prophylaxis of Malaria: the Best Forms of Quinine to administer.

The Société de Thérapeutique recently appointed a committee (MM. Adrian, Bârdet, Berlioz, and Boymond) to report on the above question. The commission concludes that the employment of solutions of salts of quinine should be reserved for active attacks of malaria. The best prophylactic salt of quinine to use is the basic hydrochlorate, it being the richest in alkaloid and sufficiently soluble. It has a less irritating action on the stomach than the sulphate. The hydrobromate should be used only in cases rebellious to the hydrochlorate. As to the pharmaceutical form in which the hydrochlorate should be administered, compressed preparations are condemned, and pills made up with a soluble excipient or *perles* provided with a gelatinous envelope are recommended. Pills or *perles* containing each fifteen centigrammes of the chlorhydrate and given one in the morning and one at night, or else before meals, suffice to keep the system under the influence of quinine so as to ward off attacks of fever. In the course of the discussion following the reading of the report it was suggested that the War Office should be urged to desist from its attempt to manufacture on a large scale compressed tablets of quinine for the use of the troops, seeing that the report was unfavourable to that method.

Arrow Poisons.

From a work by Dr. Lewin of Berlin, which work was analysed by Professor Brouardel at the Académie de Médecine (Jan. 8th), it results that the Semalis dip their arrows in a black substance called *waba*, extracted from a plant of the family Apocynaceæ. The Walaita employ crystallised wabaine, a product already studied by Fraser; other tribes of Central Africa use either amorphous wabaine or strophanthus, or a mixture of several other poisons. In Asia the poison employed for the purpose is generally aconite. In Tonkin several French soldiers were wounded with arrows dipped in the juice of *antiaris toxicaria*. M. Berthelot mentioned that certain tribes employed animal toxins as arrow-poisons, whilst others covered their arrow-tips with the excrement of certain animals.

Up-to-date Medical Advertising.

Visitors to Paris will be familiar with the advertisements with which the walls of the *chalets de nécessité* and such like useful structures are liberally supplied. From a perusal of these they learn that certain diseases can be cured by Dr. N. (dr. Speaks english, *sic*) in a surprisingly short time and with the greatest ease. But it has been reserved for the present year to show us the length to which such effrontery can go. On the drop-curtain of a certain theatre there may now be read, between two other advertisements relating to beer and pinces-nez, the following: "Docteur-Médecin Spécialiste, 25 années de pratique, de midi à neuf heures du soir." Then follows the address.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Debate on the Antitoxin Treatment at the Berlin Medical Society.

THE most important event in Berlin medical life has undoubtedly been during the last few weeks the debate on the antitoxin question, which has already been alluded to in the pages of THE LANCET; but its importance warrants my returning to the subject. The paper read by Professor Behring at the Vienna meeting of the German Association, which was immediately afterwards telegraphed to all parts of Germany, excited public opinion to something the pitch evoked by the publication of Professor Koch's results with tuberculin. Wherever a child was taken with diphtheria the medical man was compelled by the parents to use the new remedy they had read of in the newspapers. The public attention was more awakened by an article Professor Behring had published in a widely read political journal entitled "Die Zukunft," in which he attacked Professor Virchow very severely. In this article he declared Virchow's pathological doctrine obsolete and prejudicial to further progress of medical science. Virchow, he suggested, did not consider a disease a distinct entity due to one specific cause, and thus to be treated by a specific remedy, but as a conglomeration of symptoms which were each to be cured separately. As it is, of course, quite unusual for medical men to dispute in political journals the astonishment at Professor Behring's proceeding was very great and general here. When a few weeks later an assistant of Professor Virchow, Dr. Hansemann, was announced to read a paper on antitoxin at the Berliner Medicinische Gesellschaft, everybody expected this would be an answer to Professor Behring's attack, and it is no wonder that the hall and the galleries were overcrowded. Dr. Hansemann first criticised the importance of Löffler's bacillus. He mentioned that it was not yet proved that this bacillus was the only cause of diphtheria as clinically recognised. There were many cases where the Löffler bacillus was missing; in the great majority of cases it has been found together with other bacilli; finally, it has been recognised in diseases like rhinitis fibrinosa, which were not to be confounded with diphtheria. Even in healthy persons its presence has been demonstrated. Concerning antitoxin Dr. Hansemann remarked that nobody had yet seen it. We only know that animals can be immunised by weakened cultures of Löffler's bacillus and that the blood of these can cure other animals attacked by the disease due to that bacillus. Professor Behring had, in his opinion, committed the error of transferring to men results obtained with animals in proclaiming that his remedy immunised, cured, and was harmless. As every practitioner knows, very often only one child in a family is attacked with diphtheria, whilst the others remain healthy. Thus it is impossible to say for certain if the immunity has been the effect of the antitoxin or not. On the other hand, several cases have been reported where patients have acquired diphtheria although injected very early with antitoxin. The remedial effect of the antitoxin was very doubtful, Dr. Hansemann considered, on the following grounds: the diminution of mortality in some of the hospitals might have been caused by the minor gravity of this year's epidemic; the presence of Löffler's bacillus being regarded as sufficient for diagnosis, many cases formerly denoted as simple tonsillitis, from which the patients would have recovered without treatment, are now classed as diphtheria; and cases where, notwithstanding an early injection, the patients have died are not very rare. All, he thought, still agreed that the cases of septic diphtheria remained hopeless, while finally the remedy cannot be regarded as harmless, as severe symptoms have been remarked to ensue upon its injection. The discussion which followed Dr. Hansemann's paper lasted not less than three sittings. Professor Bergmann, who spoke first after Dr. Hansemann, declared that he was contented with his results obtained by the treatment, although he had begun it with a certain scepticism, natural after his bad experiences with tuberculin and tetanin. He had no doubt that Löffler's bacillus, found by him in 450 out of 470 cases, was the cause of diphtheria. Professor Virchow, who rose next, defended with great warmth the new method. The surprise at this was very great, because it was generally believed—and natural to believe—that Dr. Hansemann had been more or less commissioned by Professor Virchow to proclaim his

(Professor Virchow's) opinion on Professor Behring's work. Professor Virchow, though he did not agree with the theoretical views concerning the specificity of Löffler's bacillus, drew the attention of the society to the fact that the mortality in the Friedrich Hospital, of which he himself is a warden, diminished as soon as the new remedy was used. Each time the supply of antitoxin failed the mortality rose again until a new quantity could be procured. Professor Hahn said that he could see no difference in the mortality between those who had been injected and those who had not, but he kept an open mind on the point because in the hospital to which he was attached, which is situated in a very poor quarter, children are usually brought in too late to be treated with any success. Dr. Baginski said that he had very satisfactory statistical records. Professor Liebrich, the pharmacologist of the University, who is known to be opposed to bacteriology in general and to antitoxins in particular, invited the society to try injections of pure serum without cultures of bacilli, a method which he believed would be successful. Dr. Aronson suggested that in many cases where the method failed the quantity of the antitoxin injected must have been too little. To sum up the whole debate, the feeling generally was that the time has not yet come to pronounce a final judgment on this important question, as it could not be clearly proved that the lowering of mortality was due to the treatment or to the milder character of this year's cases. But all were agreed that the complications reported by Dr. Hansemann as following upon the treatment were of no importance, and that no patient had come to any harm by the injections. It was a subject of general remark that none of Professor Koch's or Professor Behring's assistants said a word in the debate.

The Reform of Medical Service in Berlin Municipal Hospitals.

In German hospitals the number of patients treated by one medical attendant is usually far greater than in other countries. Especially has that been the case in the Berlin municipal hospitals. There were until last year only one staff surgeon and one staff physician in these hospitals, and they, with the assistance of their resident medical officers, had each the care of 300 patients. They could, of course, not personally see so great a number every day, and were thus compelled to confine their ministrations to the graver or more interesting cases. Last year this arrangement was modified, and twice the number of surgeons and physicians were appointed to the staffs. At a meeting of the Municipal Council, where this question has been ardently discussed, some members wished to have a larger staff, with subdivisions in treatment—i.e., special wards for the eye, the throat, gynaecological purposes, &c.—but the expense was considered too high. It is remarkable that all there, and for that matter other hospitals in Berlin are not used for purposes of teaching, which is confined to the Royal Charité and the University clinics. As the number of students in Berlin increases every year practical study of disease becomes more and more difficult, and it is hoped that all the hospitals will be opened to students.

Jan. 16th.

ROYAL METEOROLOGICAL SOCIETY.—The annual meeting of this society was held on Wednesday evening, the 16th inst., at the Institution of Civil Engineers, Great George-street, S.W., Mr. R. Inwards, F.R.A.S., President, in the chair. Mr. Inwards, in his presidential address, dealt with the subject of Weather Fallacies, which he treated under the heads of Saints' Day fallacies, sun and moon fallacies, and those concerning animals and plants. He also referred to the almanac makers, weather prophets, and impostors who have from time to time furnished the world with fit materials for its credence or its ridicule.

At a special meeting of the board of management of the Chelsea Hospital for Women held on Wednesday, the 16th inst., the following appointments were unanimously made to the medical staff:—Physicians to in-patients: Wm. Duncan, F.R.C.S., M.R.C.P., M.D.; and W. H. Fenton, M.D., M.A. Surgeon to in-patients: Robert O'Callaghan, F.R.C.S.I. Physicians to out-patients: J. Inglis Parsons, M.D., M.R.C.P., M.R.C.S.; A. E. Giles, M.D., B.Sc., M.R.C.P.; and T. W. Eden, M.D., C.M., M.R.C.P. Pathologist: E. J. Maclean, M.D., C.M. Registrar: G. H. A. C. Berkeley, M.B., B.C., M.R.C.S.

THE INDIAN MEDICAL CONGRESS.

THE SECTIONS.

MEDICINE AND PATHOLOGY.

DEC. 24TH, 1894.

Presidential Address on the Fevers of India.

SURGEON-LIEUTENANT-COLONEL ALEXANDER CROMBIE, M.D., delivered his presidential address on the Fevers of India. He said:—"The fevers of India divide themselves into two great classes or groups. In the first of these are those fevers whose course is interrupted by more or less perfect periods of apyrexia, and are, roughly speaking, amenable to treatment by quinine. These are the malarial fevers. In the second group are the continued fevers, in which quinine is of no avail. With regard to the first our knowledge is precise and almost complete; with regard to the second it is still hazy and to a large extent conjectural, and yet it is in this second group that are found the fevers the fatal character of which goes so far to swell the death-rate of India to its huge proportions. I will speak first of the fevers in which periodicity is the distinguishing character—namely, the malarial fevers. With regard to intermittent fevers we are all of one mind, and there is no question, and can be no question, as to their position; but of late years there has arisen a good deal of doubt as to whether there is any specific fever which can be called remittent, and, if so, whether it should be included among malarial fevers. I confess myself among the sceptics.

"Beginning, then, with those fevers which in their normal or typical manifestations have distinct periods of perfect apyrexia—namely, the intermittent fevers—I would point out in the first place that they do not in India follow the same order of frequency as they do in other malarial countries. In those parts of India in which I have had opportunities of observation quotidian ague takes the first place in order of frequency. At most seasons I would not probably be wrong in saying that 90 per cent. of the cases of ague we have to treat have daily paroxysms of fever, and not more than 10 per cent. are tertian in type, while quartan ague is so rare that it may be practically left out of account. I have only had to treat one case of quartan ague in the whole of my twenty-two years' service in India, though I heard of another case a few weeks ago, but was unable to see it. In other malarial countries the order of frequency is quite different. In the Roman Campagna, for instance, the majority of the cases are tertian, then come quartan, and last of all quotidian agues. To this fact, the comparative infrequency of tertian and quartan ague, I attribute the reluctance which is still shown in some quarters in India to accept the amoeba of Laveran as the true pathological cause of the symptoms of malarial fever, because in quotidian ague the amoeba is often difficult to find, for the reason of its small size, its often indistinct form, and because it does not go through all the phases of its cyclical life in the blood of the general circulation. In tertian, and specially in quartan, ague it is of large size, well pigmented, and generally requires no great search to find it, and in quartan ague its whole life history can be followed in blood taken at intervals from the finger. To study the most critical part of the cyclical life of the parasite in tertian and quotidian ague—namely, the periods of segmentation and sporulation—blood must be taken from the internal organs. From these remarks you will guess, and I may as well at once confess, that I am a convert to the amoebic theory of malarial fever. It seems to me that it is impossible to offer any longer a reasonable resistance to this theory. Malarial fever is found to exist in widely different parts of the world—in America, Africa, Asia, and Europe—and in localities differing from each other in every particular of climate. Yet under all these varying conditions the phenomena of malarial fever are identical and point to an identical pathological cause. In all these places an examination of the blood of patients exhibiting these symptoms discloses the presence of a living organism which is the same in each place, the same in Africa and America as in Bombay and Calcutta; furthermore, the cyclical growth and development of the parasite are found to correspond with the cyclical periodicity of the fever, the apyrexia corresponding with the appearance of the young amoebae in the corpuscles and the accession of fever with their sporulation and the discharge of their presumed toxins into the blood. If it is to Laveran we owe the discovery of the relation of the amoeba to malarial

fever, it is to Italian physicians—and especially to Golgi, Marchiafava, and Bignami—that we owe the working out of its life history, and it seems to me impossible to resist their conclusions. Golgi has made quartan ague his special study, and the ease with which the life of the amoeba of that form of ague can be studied in the blood of the finger makes it very enticing. Its cycle of life is shortly as follows, and I am glad to have this opportunity of saying that I was able, even with my very imperfect observations, here in Calcutta, to confirm those of Golgi and Marchiafava, as far as I could do so in the single case of quartan ague which came under my observation last year. On the first day of the apyrexia the amoeba will be found, perhaps, two or even three in a single field of the microscope as in my case, occupying about three-quarters or one-fifth of the invaded red blood corpuscles and exhibiting active amoebic movements. On the second day of apyrexia it will be found that it has grown so as to occupy half of the blood corpuscle, to have become pigmented at the periphery, and to have all but lost its motility. On the third day of apyrexia it will be found to occupy nearly the whole of the corpuscle, and that the pigment has collected towards the centre preparatory to segmentation. The next and last stage of the cycle of life is that of sporulation, and with the discharge of the spores, and the toxins which the amoeba is supposed to form, comes the sudden accession of fever on the fourth day. When this happens over and over again, the same relationship being repeated between the growth maturation of the amoeba and the periods of apyrexia and pyrexia in the patient, it becomes irresistibly borne in on one that they bear an intimate and, indeed, causal relationship to each other. The study is more difficult in tertian and most difficult in quotidian ague, because the amoebae of these forms of ague cannot always be found in the blood of the finger, retiring as they do to the spleen, brain, and bone marrow to undergo their final stages of segmentation and sporulation prior to a renewed accession of fever, and indeed it is sometimes only on post-mortem examination that the important part they played in the phenomena can be understood, the number of amoebae in the general circulation not being always proportionate to the severity of the symptoms. All that is wanted to satisfy the most exacting demand for complete evidence that the amoeba of Laveran is the very cause of intermittent fever is that it should be cultivated outside the body in some suitable medium, and that when a pure culture so obtained is injected into the body of an animal susceptible to the disease it should give rise to the symptoms and pathological changes of intermittent fever. Hitherto the amoeba of malarial fever have baffled every attempt of this kind if it be not true, as was reported a few months ago, that Celli of Rome has succeeded in growing them in some alkaline medium. It would require a much more prolonged and continuous study than it has been in my power to give to this subject before I could say or ask you to believe, with Marchiafava, that each form of malarial fever has its own variety of the parasite, and that you can tell by its microscopic characters which variety is present and that the specimen of blood is taken from the finger of a patient suffering from quotidian, tertian, or quartan ague as the case may be; but it is my firm belief that there is little difficulty in doing so, and my own observations here in Calcutta, as far as they go, entirely confirm the observations of the great Italian observers, as may be gathered from the phrases I have used in speaking of the parasites of the different forms of intermittent fever, as if they were distinct. I have now seen every form of the amoeba, both the endoglobular and the ectoglobular bodies belonging to the semilunar group, with the exception of the flagellate forms in patients in the General Hospital in Calcutta, and they exactly correspond with what I saw in Rome and is described and pictured in Marchiafava and Bignami's book; and not only so, but the variety described as that of quartan ague was found existing alone in my case of quartan ague I have alluded to. Here the commonest variety is the annular form found in our cases of quotidian ague, exactly like that found in cases of quotidian ague from the Roman Campagna, and the same correspondence will be found also, I believe, in the tertian ague of the two countries.

"I now pass to those cases of malarial fever in which there is no distinct intermission. These form an important proportion of the cases of fever treated under the name of remittent fever, and allow me to say at once that we all recognise two kinds of remittent fever—a malarial and a non-malarial form, which latter I, however, regard as a continued fever, and will consider later as one of the group of

continued fevers. But at a certain season of the year—that is, from the middle of September to the end of December—in Lower Bengal, at least, a very large percentage of cases of remittent fever partake of a different character—that is to say, they are clearly of a malarial nature, and are equally with the varieties of intermittent fevers mentioned before amenable to treatment with quinine. There is little room for doubt that this group of fevers, the malarial remittents, is also produced by the same amœba forms as produce the intermittent fevers, and that they are, in fact, intermittent fevers in which either the pyrexial stage is unduly prolonged, owing to the excessively toxic qualities of the organism, so that a new accession of fever comes on before the previous attack has entirely subsided, giving time only for a small remission of the pyrexia previous to the next accession; or they are cases in which there are at one and the same time two sets of organisms in the blood whose cycles of life are parallel but not synchronous, one maturing, sporulating, and discharging its toxins some eight, ten, or twelve hours after the other, thus keeping up a continuous condition of pyrexia. Just as there is a double certian, so there may be, and in certain of the cases I refer to there is, a double quotidian, producing the phenomena which constitute what is described as malarial remittent fever. I have not made a sufficient number of observations to verify those of Marchiafava, who has found corroboration of this theory of malarial remittent fever in the existence of amœbæ in different stages of cyclical growth in the same drop of blood; but I have found the annular forms of the amœba present in cases of remittent fever in no way to be distinguished from those so constantly found in the quotidian form of intermittent. I confess, however, that these are most trying cases to investigate microscopically, at least in the time usually at my disposal for these purposes; and I have in many cases been obliged to form my diagnosis on general clinical symptoms. We must, therefore, in many cases fall back on general symptoms in differentiating the malarial from the non-malarial form of remittent fever, and the clinical features on which we must depend to justify the diagnosis of an element essentially malarial in these cases are the following: (a) the history of a distinctly intermittent character of the symptoms at an earlier stage before they become remittent in type; (b) the existence of a more or less distinct remission of the pyrexia at a fairly regular time of the day or night; or (c) the occurrence of two remissions, however slight, and two exacerbations in each period of twenty-four hours, suggesting the existence of two sets of organisms maturing separately. Observations of this nature require the most intelligent care and record, but when one or other or all of these phenomena are present you know that you are dealing with a case of malarial poisoning and you must exhibit the antidote even though no malarial organisms can be found in the blood of the finger. If when the time of my leaving India comes I were to leave a message to my professional brethren here it would be this—treat your cases of malarial remittent with quinine early, in full doses, with a free and fearless hand, and regardless of the temperature. But while I yield to no one in my advocacy of the freest use of quinine in malaria, at the same time I deprecate and deplore that indiscriminate use of it in unsuitable cases which has brought this invaluable drug into so great disrepute among the natives of this country, and has given rise to a dread of it, both on the part of patient and practitioner, which effectually prevents its effective employment in cases where it is the only hope of salvation. In this instance, as in every other, a careful diagnosis is essential. If after a painstaking inquiry the case appears to be one of the second group of which I am about to speak, the group of continued fevers, withhold quinine or give it sparingly and tentatively; but if you come to the conclusion that the case is malarial you cannot give it too freely or fearlessly, or with too lavish a hand.

"I now come to the second group of fevers, our knowledge of which, with perhaps one exception, is unfortunately still vague and conjectural, and in which quinine is not only of no avail, but is sometimes distinctly harmful. I refer to the continued fevers, of which I recognise with certainty three, and probably five, as specifically distinct. The three whose differentiation I regard as indisputable are simple continued fever, typhoid fever, and non-malarial remittent, so called; of the other two, whose title to a distinctive name you may be disposed to doubt, one is a fever especially of towns, known locally as 'Calcutta fever,' 'Bombay fever,' &c., which runs a course very similar to that of typhoid fever without

any of the symptoms of that disease; and, lastly, there is a low continued elevation of temperature of indefinite duration and without any distinctive symptomatic features, and known simply as 'low fever.'

"Many cases wrongly returned as 'ague' are really cases of 'simple continued fever.' If, instead of determining within a week, the fever, as is not very unusual, especially during the cold season and early summer, continues for a longer time, we look for defervescence about the fourteenth, twenty-first, or twenty-eighth day. These cases are particularly common in towns and are known as 'Calcutta fever,' 'Bombay fever,' &c., and it is open to anyone to assert that they are cases of mild typhoid fever, and that those which recover early are merely abortive cases of that disease. But I am one of those who are unable to admit that the whole philosophy of continued fever in India can be epitomised in the word 'typhoid.' I cannot admit that the bacillus of Eberth is the only organism capable of giving rise to a febrile curve of three or four weeks' duration."

[Here Surgeon-Lieutenant-Colonel Crombie went carefully into the diagnostic points of enteric fever. He continued:]

"I maintain that we are not justified in designating as typhoid fever cases which have neither the gradual initial rise, nor the eruption, nor the characteristic stools, whether loose and like pea-soup or constipated and like yellow coach paint, cases in which the tongue continues clean and moist or simply coated as in any febrile condition, and in which the mind is clear throughout unless you give quinine. I say we are not justified in calling such cases, in which all the symptoms of typhoid fever are absent, enteric fever simply because they have a duration of three or four weeks. I demand that some one or more of the ordinary symptoms of typhoid fever should also be presented. Neither will I admit that even hæmorrhage from the bowel necessarily removes them to that category if it be true that other febrile infections besides that of typhoid fever may also give rise to intestinal ulceration. I believe that the cases which I am now describing, and which are so sharply differentiated from typhoid fever by the whole clinical picture which they present, constitute a specific disease and must have a specific and separate cause distinct from the bacillus of Eberth.

"A very few words will suffice to dispose of the next form of continued fever. It is one which is only occasionally met with among Europeans, and I do not think I have met with it in natives of India; but if it does occur among them it would hardly be brought under my notice. I refer to a persistent low elevation of temperature unaccompanied by any constant symptoms, of indefinite duration, and uninfluenced either by quinine or arsenic. The temperature never falls below 99° and rarely rises above 101.5° F. It may continue for several weeks without complication, except perhaps a tendency to diarrhoea of a bilious character, with loss of appetite and gradual loss of strength and flesh. Some of these cases are distinctly aggravated by quinine, and I have known them to cease abruptly on withdrawing the drug, which had been persistently given in the belief that the condition was malarial in its essential nature. These cases are spoken of as 'low fever,' and are generally cured by a 'change' of any kind, but especially by a trip to the sea; and it is especially this form of fever which in Calcutta is benefited by a visit to the Sandheads. Though very ill defined, these cases contain a distinct type of fever at once recognised when met with.

"Widely different from this 'low fever' is the last form of continued fever of which I have to speak—namely, the non-malarial remittent (so called). It is a pity we have no better name for this fever, which is of very frequent occurrence, and is one of the most fatal of our fevers. The designation 'remittent' is a misnomer. It is no more remittent—and, indeed, is often less so—than typhoid fever. The temperature is generally very high, touching 104° and 105° for a long part of its course, the daily fluctuation not exceeding 2° or 2.5°. It begins in a way not unlike the cases I have described under the names of 'Calcutta fever,' 'Bombay fever,' &c., and is by some considered to be a variety of typhoid fever notwithstanding its divergence from all the symptoms of that disease. Hepatic enlargement and congestion are early and constant conditions, but the spleen as a rule continues impalpable below the ribs. Bilious diarrhoea, in no respect resembling the diarrhoea of typhoid fever, is also a very frequent symptom. Quinine often given in large and repeated doses in these cases is not only not useful, but so obviously adds to the distress of the patient, without in any way producing an improvement

in the progress of the symptoms, that it is very soon abandoned. Meanwhile, the temperature continuing persistently high, marked head symptoms, especially delirium of a muttering and irritable kind, comes on, and the patient may even, and often does, pass into a condition of coma from which he can hardly be roused. This condition, one of persistent high temperature without any marked remission, a distinctly enlarged and congested liver with bilious diarrhoea, congestion of the back of both lungs, and a low muttering delirium, is generally reached by the eighteenth to the twenty-fourth day. If coma supervenes the patient frequently dies about this period. In more favourable cases where the symptoms are less severe they continue for a week or two more, and the average duration of the case is six weeks. None of our drugs seem to be of any use in shortening it, certainly not quinine, the inadequacy of which in these cases has now become fully recognised, though the disease has not yet found a name or place in our nomenclature."

[Surgeon-Lieutenant-Colonel Crombie concluded with an eloquent appeal to his medical hearers not to allow France and Germany to remain in the van of bacteriological research, but to make a more careful clinical study of the cases which came daily under their observation in India, the enormous field for clinical study in which he had worked.]

PROCEEDINGS IN SECTION.

DEC. 28TH, 1894.

THE following are abstracts of papers read at the Congress:—

A Case of Lymphadenoma (Hodgkin's Disease) in a Native.

Dr. J. CHAYTOR WHITE read a paper under the above title. He said: "The comparative rarity of this disease in the native of India is my apology for bringing a case before the Congress, it being the first I have seen in this country. The patient, a man aged thirty-six years, a native of this district, was admitted into the Mozuffarnagar Dispensary on July 19th, 1894, suffering from a series of multiple enlargements of all the superficial lymphatic glands of the body. He first noticed a swelling in his armpits a year ago, and in the following October the inguinal glands on both sides became affected. About three weeks ago he noticed swellings under the jaw and around the neck, when deglutition became difficult and his health bad. He had not suffered from syphilis. On examination it was evident that every palpable group of lymphatic glands was affected. The cervical chains were all enlarged, but had not become aggregated. The submaxillary, sublingual, and parotid glands of both sides were greatly enlarged and conglomerate. The adenoid tissue of the pharynx and fauces was involved, and the tonsils when palpated felt like almonds. The voice was hoarse and there was difficulty in deglutition, but the recurrent laryngeal was not paralysed by pressure. The thyroid was much enlarged, and the mediastinal glands were also manifestly involved. The mesenteric glands were easily felt on palpation, and from the enlarged retroperitoneal and lumbar glands of the left side there was a copious discharge of lymph, which found exit at the bottom of the abdomen above Poupart's ligament. There was no evidence of change in the thymus, nor was there any caseation or suppuration in any one of the enlarged glands. The spleen was considerably increased in size, smooth on the surface, and could be felt well below the ribs. The urine was normal. The blood was found to be distinctly deficient in red cells, which were only about 53 per cent. of the normal. Leukæmia was marked, there being an excess of white cells in the proportion of about 1 white to 75 red. Thered cells were also poor in hæmoglobin, it being estimated at about 45 per cent. of the normal. On staining a specimen after Ehrlich's method with eosine and logwood the eosinophile corpuscle was not found to be present. The temperature throughout the case under notice was of the curiously characteristic hectic type. It never exceeded 102° F. and never quite touched the normal curve. No febrifuges were administered for its control. I gave thyroid gland tabloids a trial, but with absolutely negative results."

The Possible Antagonism between Malaria and Phthisis.

Mr. ARDASHEER DOSSABHOY COOPER, M.R.C.S. Eng., &c., read a paper on the Possible Antagonism between Malaria and Phthisis. He commenced with a reference to the small amount of attention that had been given to this subject, notwithstanding its importance, and then continued: "As late as 1811 it was put forth by Wells that malaria and phthisis were opposed to each other, and he cited many

authorities in support of his views. In 1841 Harrison of Horncastle remarked on the infrequency of phthisis in the fens. These views were revived in 1856 by M. Bedouine, who held that malaria and phthisis were opposed to each other. He formulated his views under three heads: '(a) that where malarial endemic fevers are prevalent phthisis is rare, and that the frequency of one class of cases is inversely proportionate to that of the other; (b) that where malaria decreases phthisis increases; and (c) that phthisis is more curable in malarious regions than in others.' Writing on this subject, the late Dr. Peacock instanced six cases in which phthisical patients under his treatment were found to be suffering from ague, thus leading him to reject the idea of there being any material antagonism between the two maladies; but he was careful to add that 'the facts do not, however, warrant the denial of the supposition altogether, and there are probably few popular ideas which have not some foundation in truth.' It has been observed by Professor Virchow that fever prevailed to a frightful extent in Silesia, where nearly everyone had enlarged spleen, but he hardly ever saw a case of phthisis, and he was borne out in this observation by all the medical practitioners in the country. Numerous American observers, as Dr. Green and others, advance views supporting the antagonism. Dr. Green has remarked that not a single case of phthisis was to be seen in his district, where paludal fevers were very common, and he observes that phthisical patients coming to the locality were much benefited and found 'relief as decided as it was permanent.' He mentions that when a morass near Rutland was converted into a pool fevers were replaced by phthisis, and on the reconversion of the pool into a morass intermitter fevers reappeared. A French writer, M. Jurdanet, in a book published in 1861, mentioned two provinces, Yucatan and Tabasco. In Tabasco fevers are very common and phthisis is rare, whereas in Yucatan the reverse holds good, and the fact is so well known and appreciated that persons suffering from phthisis are ordered to Tabasco by their medical advisers. Dr. R. W. Felkin, Lecturer on the Diseases of the Tropics in the Edinburgh School of Medicine, in his travels through Central Africa, where he had exceptional and varied opportunities of observing the prevalence of malaria and phthisis, seems to have come across very few cases of phthisis, and even these corresponded in a very remarkable manner with the absence of malaria. In the swampy districts of Unyoro and Uganda he met with but few cases of phthisis. The same was his experience in his journey from Khartoum to the Albert Lake along the Valley of the Nile. However, while returning he saw a large number of cases in the district of Shuli at an altitude of from 3000 to 4000 feet, where malaria is rare. Throughout this paper no mention whatever has been made of India, where both the diseases are found. I will not venture to determine whether the malarious parts of India are absolutely or comparatively free from phthisis, and whether the malarious localities are more favourable residences for phthisical patients."

The Prophylaxis of Malarial Fevers.

Surgeon-Major N. DUNCAN, M.D., B.S., F.R.C.S., read a paper on the Prophylaxis of Malarial Fevers, in which he said: "I propose, with regard to the prophylaxis of malarial fevers, to offer, first, a short *résumé* of the opinions of medical officers of our own and other countries; and, secondly, to narrate the results of my own experience, restricting myself to the question of preventive drugs. Amongst the French physicians, M. Corré holds it still unproved that the practice of keeping the system under the influence of drugs intended to kill the malarial organism is beneficial. M. Kelsch and M. Kiener state that the officers of the French marine favour the exhibition of quinine. Coming now to the Italian physicians notable results have been obtained by Tommasi Crudeli. This physician experimented with other drugs than quinine. In 1880 he began to try the effect of arsenic with encouraging results. Dr. Ricchi in 1883 tested its action in the case of 78 persons in the district of Borino, where malaria is very rife: of the 39 who took it 36 escaped entirely, while the 3 remaining had only slight attacks; of the 39 who did not take it the great majority had severe attacks of fever. Again, in 1885 657 persons were experimented upon. Of these, 402 gave good results, 119 pretty good, whilst the effect was indifferent in 138. Tommasi Crudeli also speaks highly of a decoction of lemon. Such, therefore, have been the results obtained by our Continental brethren. With regard to America, we have the experience derived from the War of the Secession. Surgeon Bryan

found quinine and cinchona to be sure prophylactics; but in all cases the experience of this war did not show that the indiscriminate use of quinine as a prophylactic was necessary. Coming now to our own countrymen, Bryson reported excellently on the prophylactic effects of quinine. On the West Coast of Africa, on the Gambia, Harvey found, however, no good results to occur. The blue-jackets who took quinine daily had as much fever as the men who did not. The late Surgeon-Major Parke, ten days before entering the mouth of the Congo, gave the officers four grains of quinine three times a day. There were only two cases of slight intermittent fever, although 350 miles of the most unhealthy region were passed through. No other white man had previously travelled the same country with the same immunity. My late friend, Dr. Ralph Leslie, whilst acting as Government medical officer in the Congo Free State, gave a protracted administration of arsenic by interrupting it during fifteen days every six weeks. Everyone who had gone regularly through the treatment was preserved from severe attacks of fever. Dr. Crosse of the Niger Company has again had favourable results from the exhibition of quinine. At Peshawur, in 1866, during the autumn the different corps were divided into wings, the men in one wing having five grains every evening, the men in the other having none. From Sept. 1st to Nov. 30th 1203 men took quinine, the admissions into hospital for malarial fever being 10.22 per cent.; 1202 men who took no quinine had an admission rate of 27.28 per cent. for fever. There is, however, evidence of a contrary kind. Sir Anthony Home did not consider quinine thus given to have any value. In the Malay War, again, a daily issue of three grains was ordered. The Goorkhas did not receive the ration, and yet they suffered only very slightly more than the Buffs, who took it; but among the Buffs the malarial fever which did attack the corps appeared one month at least after they had been regularly taking it. I will conclude my paper with a brief *résumé* of my own experience. The men from whom my results have been obtained are Sikhs and Goorkhas. The drugs I have given have been quinine, quinetum, cinchona febrifuge, cinchonidine, sulphur, arsenic, and atees. Atees, I found on inquiry from my hospital assistant, was a favourite drug among the native community for ague. With regard to arsenic, I have found no benefit to follow its use. During 1836 and 1837 I placed the men of the regiment I was serving with on a prophylactic ration of arsenic during the months most liable to malarial fever. In 1836 four companies of the 23rd Pioneers were ordered arsenic, commencing with five minims twice a day, finally taking ten minims of the liquor three times a day. From August to December there were fifty-four cases of malarial fever in all. In the companies taking arsenic twenty-eight cases occurred; in the companies not taking it twenty-six. In 1837 the men of the 14th Sikhs were subjected to a similar treatment from Sept. 20th to Nov. 16th. The right wing took six minims of the liquor twice daily, the left none; the right wing had eight cases of ague, the left nine. In 1839, whilst in charge of the 14th Sikhs at Peshawur, the regiment having suffered to an unusual extent from malarial fever during the preceding year at Jhelum, I again tried the prophylactic effect of arsenious acid from Aug. 16th to Oct. 30th. Here, again, arsenic had no prophylactic effect; if anything, the companies not taking it were rather freer from malarial fever. Thus the malarial fevers in India are either not so amenable to prophylaxis by arsenic as those of Italy, or else the form in which the preparation was given was the cause. Tommasi Crudeli does not recommend the liquid preparation of arsenic, but gives the drug in the solid form in gelatine tablets. With regard to quinetum, the results are not sufficient to draw any conclusion from. Turning now to the effects of quinine and cinchona febrifuge, A and B Companies from Aug. 2nd to Oct. 31st took respectively three grains, increasing in the last week to five grains, of quinine and cinchona febrifuge. Up to the week ending Oct. 10th, when E, F, G, and H Companies took quinetum, the results were:—

A Company,	taking quinine,	10 cases of malarial fever.
B Company,	taking cinchona febrifuge,	11 " "
E Company,	" "	24 " "
F Company,	taking no drug,	18 " "
G Company,	" "	21 " "
H Company,	" "	13 " "

Here we see, therefore, a decided prophylactic effect was exercised. Finally, coming to the results obtained during the year 1894 amongst the 1-3rd Goorkha Rifles with quinine, cinchonidine, sulphur, arsenic, and atees, I regret to say that I have none of any value to offer. The result of my

experience is, then, that of all the drugs named quinine and cinchona febrifuge are the only ones that have exercised any influence."

The Macro-Pathology of Constitutional Malaria, with Special Reference to its Treatment by Alkaline Saline Mineral Waters.

Surgeon-Major L. T. YOUNG, M.D., I.M.S., in his paper under the above title, said: "Before discussing the use of alkaline salines in the treatment of malaria it will be necessary to very briefly consider the pathological condition produced by malaria and their functional effects. Even a rather casual inspection at numerous necropsies will, I think, lead to the adoption of the opinion that malaria congests the internal organs and causes catarrh of the mucous membranes. A proper recognition of these two facts and their results may be considered the key to the successful treatment of the constitutional effects of malaria. Is it not rare at an Indian necropsy to find a liver free from congestion of some form or other? In many instances the appearances are distinctly those of incipient 'nutmeg' congestion, whilst in advanced malarial cases there is distinct cirrhosis of a hypertrophic kind, following to some extent as the result of long-standing congestion, according to the well-known pathological law. This cirrhosis is not the ordinary 'hob-nailed,' contracted surface form, but the enlarged, hypertrophic, morocco-leather surface form, which commences in and around the bile-ducts, and which, I venture to suggest, begins as a catarrh of these channels in a manner similar to that in which catarrhal malarial enteritis supervenes on tropical intestinal catarrh. Tropical hepatic congestion is always associated with more or less fatty infiltration of the liver cells. The acute results comprise hepatitis, abscess, perihepatitis, dysentery, catarrh of the bile-ducts, &c. The chronic results embrace the various forms of imperfect proteid metabolism or liver indigestion, also gout, rheumatism, and possible diabetes, &c. The early congested and the late cirrhotic stages of the spleen are only too well known. The organ or its capsule sometimes becomes inflamed; the enlargement of the organ may reach an enormous size, sufficient to almost fill the entire abdomen. In the later stages ascites supervenes, anæmia and debility, with a tendency to sudden death from pulmonary thrombosis, as so ably described by Sir Joseph Fayrer. These kidneys are nearly always found congested, often intensely so. Of the later stages, the large white kidney has been the most frequent result of my own observations, not the cirrhotic form as one would have expected. Acute desquamative nephritis is not a rare complication of severe malarial fevers, and it is often in the slightest degrees overlooked, and gradually assumes the fatal chronic form. The dietetic errors to which Anglo-Indians as a class are so much addicted are also largely to blame for many cases of Bright's disease. All the mucous membranes of the body become sooner or later affected by catarrh from malaria and residence in a tropical climate. Pharyngeal and laryngeal catarrhs are generally the earliest to occur. The latter spreads with great frequency up the Eustachian tube, giving rise to otitis media, which often goes on to suppuration with loss of the membrana tympani and ossicles, or to plastic inflammation sealing up the ossicles into the fenestræ and so causing deafness. The Schneiderian membrane shares the same fate, and hyperplasia of it over the turbinated bones is a common result. Slight chronic ophthalmia attacks the conjunctivæ. The lining of the uterus becomes endometritic. The most important catarrh, however, is that of the stomach and intestines. Under the influence of repeated 'long drinks,' large meals, and hot weather the stomach becomes dilated, its glandular structures degenerate and atrophy, leading to the secretion of gastric juice imperfect in quality. You may, perhaps, have observed that an ague patient who has had a drink of milk half an hour previously brings it up perfectly uncurdled, showing the complete absence of acid from his stomach. The thickly loaded, large, flabby, indented 'tropical tongue' is a frequent sign of tropical gastric catarrh. The intestinal catarrh often causes, not alone obstructive jaundice, but ramifies and extends along the bile passages in its more chronic forms. This, as I have already suggested, may act as the starting point of biliary cirrhosis. Catarrhal enteritis is a common and extremely fatal consequence of extension of intestinal catarrh to the substance of the intestine from its mucous membrane, and its occurrence is favoured by the mechanical obstruction to the return of blood from the chylipoietic viscera by a chronically congested liver. This enteritis is not a sthenic form of

inflammation accompanied by the exudation of lymph, nor does it usually excite the overlying peritoneum to effusive inflammation. The bowel—usually found pale, thinned, and anæmic from malarial atrophy—is, when enteric, found darkly congested, thickened, and its mucous membrane soft and vividly injected. The peritoneal side of the bowel is also red and injected. Long tracts of the bowel are not affected in this intense manner, but only patches of a foot or two. The spaces between these present all the signs of chronic congestion or of incipient inflammation, with signs of vascular dilatation and blood stasis. The congestion is usually most marked about the ileum. There is no trace of any ulceration of Peyer's patches or of the mucous membrane. A patient who recently died at the Umbala Hospital from this affection had grass-green diarrhoea, just like a child with irritative diarrhoea. The colour of the motions in diarrhoea is mostly either pale or dark. I have not often seen it green in adults. Malarial degeneration or atrophy of the heart also occurs in advanced cases. This organ is found pale, thin, small, and flabby. The ventricular walls are reduced to about half their normal thickness. There are atrophy and fatty degeneration of the muscular tissue. Severe and long-continued malarial fevers often produce paresis or paralysis, motor or sensory, or both, of the lower limbs. This was found to be due to spinal pachymeningitis. We next come to the question of how the above conditions may be ameliorated, removed, or prevented by alkaline saline mineral waters. Of these the chief are those of Neuenahar, Carlsbad, and Marienbad."

[Surgeon-Major Young here described the composition and action of Carlsbad water, both natural and artificial. He then continued:]

"Patients must be prepared to devote two hours each morning to drinking the water in the proper manner. On getting up in the morning a dose of six ounces and a half of the natural or artificial water made from the salts and warmed to a temperature of 120° F. should be slowly sipped as it cools down. After this a walk of twenty minutes in the open air is taken, and then another six-ounces-and-a-half dose; a second walk of twenty minutes, and a third similar dose are next indulged in. This is followed by a walk of one hour, after which the patient can have a simple breakfast. Some patients are given an extra dose of the water at 11 A.M. and another on going to bed at night. This latter has a great effect in cleaning the thickly furred 'tropical tongue.' During the course the following articles of diet are strictly excluded: fresh fruit, salads, acids, cheese, tinned, dried or smoked fish, and butter. Sweets, greasy dishes, and strong wines or short drinks are also to be avoided."

Typhus Fever in Hoti Mardan and in Beluchistan.

SALVATOR ALOYSIUS PISANI, M.D. Edin., Chief Government Medical Officer, Valetta, Malta, read a paper on the above subject, in which he said: "Typhus fever is no new disease in India. Anybody who has had occasion to refer to Dr. Bryden's Statistical Report, published in 1878, will, I think, feel convinced that some, at any rate, of the outbreaks described by him were instances of true typhus fever. The improved sanitary condition of our gaols in recent years has led to the disease being less frequently observed, to our forgetting the work of our predecessors, and to our doubting even the prevalence of typhus fever in India. I think that we have accumulated evidence to show that this disease is endemic in certain parts of India, where climatic conditions in some seasons of the year approach to those of European countries. In fact, we might call this an endemic area, and include in it the trans-Indus districts from Beluchistan to Kusufzai, the Hazara, and Rawalpindi districts, and the Himalayan hill tracts. The first of the two outbreaks which I will bring to your notice occurred in the magistrate's lock-up at Hoti Mardan in the Peshawur district during the months of April, May, and June, 1888. During the month of May and in June I had an opportunity of observing seven cases of typhus fever among the prisoners, and two cases among the constables who had formed part of the guard over the sick prisoners at the Mardan Dispensary.

"Case 1: The patient was admitted to hospital on the seventh day of illness. When seen on the morning of the eighth day there was commencing rash over abdomen, delirious; eleventh day, rash extensive over side of chest and abdomen, semi-conscious; fourteenth day, temperature normal, rash dark purple; fifteenth day, rash still present; I have no note when rash disappeared; eighteenth day, conscious for first time; twentieth day of illness appeared deaf; twenty-third, still deaf; constipation throughout.—Case 2: Seen on eighth day, was then delirious, semi-comatose; slight commencing rash; eleventh day, rash evident, but scanty on side of abdomen and chest of purple colour;

fourteenth day, temperature normal; fifteenth day, rash disappeared; seventeenth to twentieth day, troubled by vomiting; twenty-second day, apparently deaf; constipation throughout.—Case 3: Seen sixth day; seventh day, two suspicious spots on abdomen, no delirium; thirteenth day, evidence of pneumonia; fourteenth day, spots petechial; sixteenth, delirium, abdomen distended, hicough; seventeenth, temperature normal.—Case 4: Seen fifth day; eleventh day, slight delirium; twelfth day more delirious, semi-conscious; thirteenth day, purple mottling over abdomen and chest; fourteenth day, temperature normal, offensive black stool; fifteenth day, delirious; sixteenth day, no delirium; eighteenth day, some petechiae visible; twenty-first day, deaf.—Case 5: Seen on second day; rash commenced on sixth day; was well marked by tenth day, slightly delirious; on thirteenth day, unconscious; on fifteenth day, temperature normal; on eighteenth day, deaf.—Case 6: Seen first day; rash commenced on ninth day; eleventh day, delirious, semi-conscious, macular purple rash, extensive over side of abdomen, over chest, and extending over the arms; fourteenth day, pneumonia, rash still present; nineteenth day, temperature normal.—Case 7: Police constable on guard over sick; seen first day, suspicious-looking spots; on fourth day, soon disappeared; sixth day, epistaxis; no note of delirium; temperature normal fourteenth day.—Case 8: Seen first day, signs of rash; on fifth day, still present; on eighth day, scanty; no note of delirium; temperature normal fourteenth day.—Case 9: Police constable seen sixth day; had been on duty over sick and been relieved; when first seen he was covered with a macular purple rash; this rash was so extensive that it extended pretty nearly all over the body, except his face; at first of a bright purple, it became gradually darker; he was delirious, semi-conscious; this man died on the tenth day of his illness.

"In the brief notes that I have given the pyrexia in the non-fatal cases lasted from the fourteenth to the nineteenth day; it was of a continued type throughout; the fever was accompanied by a distinct measly purple rash, very extensive in Cases 6 and 9, evident in Cases 1 and 5, and in Case 3 when the mottling subsided, scanty in Cases 2 and 3, and practically absent in Case 7. The rash commenced in one case on the fifth day, in one on the sixth day, in one on the seventh day, and in one on the ninth day. In all these cases there was an opportunity of observing the patients previously to the days mentioned. In three cases the rash was present when the patients were first seen—one on the sixth and two on the eighth day. In the case where mottling was noted it appears to have occurred unusually late—namely, thirteenth day; at any rate, I have no notes of its being visible before this date. Delirium of a low kind was present in seven out of the nine cases, accompanied in many of the cases by great prostration and more or less unconsciousness. In two cases there was pneumonia, occurring on the thirteenth or fourteenth day of the disease, and in every other case there were more or less signs of bronchitis. Sir George Buchanan, in his article on Typhus Fever in 'Reynolds' System of Medicine,' says that 'symptoms referable to the respiratory system are so common and so important that they must be regarded as essential parts of the disease.' In every case, both in this outbreak and in the cases I shall relate presently, the frequency of these respiratory complications constituted an additional danger to the disease. Constipation was a prominent feature in most cases; marked tympanites was present in three cases; troublesome vomiting during convalescence in one case. In four cases there was marked deafness, lasting for some time during convalescence; and in the case of the constable, where there was no rash, there was epistaxis on the sixth day, about the period a rash would be expected. To prove the contagiousness of this fever we have (1) the evidence that two constables on guard over the prisoners contracted the disease, one dying; (2) the importation of the disease to the Peshawur Gaol. It was due to some prisoners suffering from fever having been transferred from the Mardan lock-up on April 28th to Peshawur that led the civil authorities, at the request of the Inspector-General of Prisons, Punjab, to ask me to inquire into the sickness prevailing at the lock-up. I reported the disease to be typhus fever on June 2nd, 1888. At the time that the sickness commenced in the lock-up, and for some time before, there had been considerable overcrowding; the barracks were very badly ventilated, the only means of ventilation being through the grated doors; in addition, the barracks themselves were in a very insanitary condition. As typhus fever is endemic in the Peshawur district and the history of the earlier cases is not obtainable, the origin of the outbreak could not be traced. The second group of cases that I will notice occurred among the coolies working in the Khojak tunnel in Beluchistan. Evidence of a very fatal contagious disease was obtainable from the excessive mortality among the hospital establishment. In 1890, out of a strength of nine seven died. In the first seven months of 1891, out of a strength of ten four died. The cases which I found prevailing after my arrival on April 19th were cases of relapsing fever, a few cases of typhus fever, and some which

did not present any characteristic features. The seven cases of typhus fever which I saw occurred, like the Hoti Mardan cases, in the months of April, May, and June.

"Case 1: Admitted April 23rd; sixth day seen; on seventh day lying on back groaning and prostrate. Sordes on lips, purple rash not raised over abdomen and lower and front part of chest; bronchitis both lungs, spleen tender; eighth day delirious; tenth delirium, now of active character; thirteenth delirium, active signs of pneumonia; sixteenth day temperature normal, complained of cardiac pain, getting more prostrate; died seventeenth day. Post-mortem examination, rash still faintly marked, signs of double pneumonia, pericarditis and meningitis, enlarged spleen and liver, temperature irregular.—Case 2: Hospital dresser taken ill; admitted April 21st; 23rd kept in his room, informed of his illness; ninth day he was covered with a very copious and a very marked measles rash, present over chest and sides of abdomen, and some on thighs and arms; on eleventh day crepitant rales, both lungs resonance, impaired; thirteenth day delirious, tongue protruded with difficulty, rash getting darker; fifteenth day, prostrate, during the night had epileptic convulsion and died; rash present after death.—Case 3: Assistant Surgeon taken ill; April 23rd, irregular temperature, rash appeared; eighth day, slightly raised at first, signs of bronchitis; on eleventh day the following note of the rash was made—it is dark purple, situated at sides of abdomen, the lower part of the sides and a few in front of chest; a few spots on flexor surface of the forearms, delirium began late; on eighteenth day had lobular pneumonia and laryngitis, temperature normal; twenty-second day, delirious up to twenty-fifth day; rash practically disappeared on eighteenth day.—Case 4: Admitted twelfth day of illness; seen on thirteenth day, very prostrate, breath foul, can scarcely protrude his tongue, intellect dull, passing motions in bed, purple rash over chest and abdomen accompanied by mottling, bronchial rales back of both lungs, resonance not clear; temperature normal fifteenth day; sixteenth day, rash and mottling disappeared.—Case 5: Admitted sixth day of illness, rash present, purplish red; eighth day rash darker, disappearing on pressure, cough; tenth day, very drowsy, sordes on teeth, cannot protrude tongue; eleventh, passing watery motions in bed, prostration marked, bronchial rales; twelfth day, delirious, temperature normal; sixteenth day, convalescent, rash faintly seen.—Case 6: A recent arrival at Khojah seen from first day; fourth day, sign of spots of reddish colour over front and sides of chest, abdomen, and back not elevated; fifth day, bronchitis; sixth day, rash, now well marked and of a purple colour, disappearing on pressure; eighth, rash does not disappear on pressure; fourteenth day, temperature normal, rash hazy; twenty-sixth day, rash very faintly visible, no delirium.—Case 7: No clear history of illness; admitted June 12th, very dull; tongue dry, brown, and black, in centre reddish-purple, rash and mottling over chest and sides of abdomen, and flexor surface of forearms; June 13th, vomited; June 14th, vomited six times; 15th, delirious at times, rash dark purple, does not disappear on pressure; June 18th, temperature normal, rash disappearing; 19th, rash nearly gone.

"Some of these cases were not typical; but I think there was no doubt of the nature of the disease."

DEC. 27TH, 1894.

On the Prevalence of the Ankylostomum Duodenale in Madras.

Surgeon-Captain C. H. WILLIAMS, M.D., in a paper under the above title, remarked:—"Of the last fifty post-mortem examinations I have made in the General Hospital, Madras (that is, since March last), in which the small intestine has been examined, this parasite has been found in twenty-six, or 52 per cent. The diseases of which the twenty-six hosts died were as follows:—Diseases of the abdomen: cirrhosis of the liver, 4; dysentery, 3; perforation of stomach, 2; cancer of stomach, 1; pancreatic abscess, 1; diarrhoea with ulcers in large intestine, 1; tuberculous peritonitis, 1; suppurative nephritis, 1; cystitis and pyelitis, 1. Diseases of the chest: lobular pneumonia, 2; pyo-pneumothorax, 1; mitral stenosis, 1. Diseases of the head: cerebral thrombosis, 1. General diseases: traumatic tetanus, 2; malarial fever, 2; starvation, 1; ankylostomiasis, 1. Besides these twenty-six cases eight were returned as ankylostomiasis by the physicians in charge of the wards, one being the case included above; and of these six were discharged cured and one relieved. As regards the nationality of the twenty-six hosts, twenty-three returned themselves as Hindus, one each as Eurasian, Native Christian, and Pariah. Two of the Hindus were Nayers from the West Coast, the rest were the ordinary Tamil coolie class, drawn chiefly from the neighbourhood of Madras, but partly from the whole Presidency, many coming long distances. The actual figures are: five born and bred in Madras, nine who had been from some weeks to a few years there, eleven who came from other parts of the Presidency direct to the hospital, and one (a beggar) who had probably been all over the district. This shows that the parasite exists both in the Presidency town and widely throughout the Presidency. The ages of these patients varied from sixteen to seventy, the average being thirty-six. The hospital admits as in-patients only males over twelve years of age, and no statistics are therefore available for women and children. The cases are returned as ankylostomiasis in which the eggs of the worm are found in the *feces* in great abundance, and no other cause is evident for the very marked anemia

from which they suffer. Usually they give a history of an anemia increasing for one or two years, with, in some cases, but not in all, a febrile onset of a few days, and usually some discomfort, doubtless duodenal, referred to the epigastrium. Of organic changes produced by this parasite I have found none certain, but in two cases changes which I was inclined to attribute to them. One was in a case which died from perforation of the small intestine high up. The perforation had taken place through a cicatricial mass, not much indurated, encircling the bowel; and the duodenum and first few feet of the ileum were found to be the seat of eleven circular cicatrices, some as much as two inches long, and most unusual in appearance. I thought, and still think, these were due to the bites of ankylostomata at some previous time which had ulcerated and cicatrised. If not, I do not know to what they were due. The case is recorded in the Transactions of the Madras and South Indian Branch of the British Medical Association for this year, a plate accompanying it. The man was not markedly anæmic at the time of death, but a few ankylostoma were present. No good history could be obtained, as he was moribund on admission. The other supposedly organic changes were a considerable cirrhosis of the pancreas, a certain amount of interstitial nephritis, and a doubtful interstitial change in the liver found post mortem in the case of ankylostomiasis. This might possibly have been produced by long-continued reflex irritation, though I am far from asserting that it was. As to the members in which these parasites are found, they are as a rule not many; but usually where they are present some bites are visible on the duodenal mucosa. Females, as usual, much predominate. The conclusion to be drawn from this is that, whereas the parasite is very commonly present among the poor natives who come to this hospital, any actual disease worthy the name of ankylostomiasis and produced by them is rare."

Radical Cure of Chronic Dysentery in its Recurrent Form.

Dr. HENRY GALLAY took the above title as his subject, and said:—"These cases show that it is possible, without much difficulty by setting aside all the therapeutic substances which are to be absorbed by the stomach, and, notwithstanding, allowing the sick persons to feed themselves as they like, to cure old chronic dysenteries, especially when this disease is assuming the form which is called 'repeating form'; and this result can be obtained simply by performing a daily and continuous series of washings of the large intestine with a solution, of which the following is the formula: nitrate of silver crystallised, 1 scruple; distilled water, 1 litre.

"Case 1: Dr. G—, a medical officer, in 1883, while residing in Tonquin, contracted acute dysentery, and during four years he had fourteen relapses of the same disease, in spite of all our known suitable treatment. After the eleventh relapse Dr. G— tried the washing of the large intestine with the above solution. Several series of ten washings each resulted at each time in a period of apparent recovery, lasting from forty to fifty days, and finally Dr. G— decided to begin an indefinite series of washings, which resulted in a definite cure in August, 1892, maintained in September, 1894.—Case 2: Mr. X—, revenue officer at Saigon, had suffered for two years from dysentery in repeating form. He had tried every sort of treatment. At Bordeaux, in June, 1892, he underwent a series of twenty washings, and then wrote to me saying that he had never been so well. In reply, I advised him to repeat the series. Since I left France I have not heard from him; but what I have learnt from experience permits me to conclude that he did not require any more aid from me.—Case 3: Miss D—, fourteen years of age, an Indian Eurasian, had dysentery in April, 1892, and was relieved in fifteen days, but afterwards suffered from constant uncontrollable stools in the morning and frequent indigestion, which gave rise to ejection of mucus and bloody matter, with tenesmus. September, 1892: series of twenty washings, complete amelioration. The series was kept up by way of precaution to the fiftieth washing. September, 1894: the cure has been confirmed since.—Case 4: Mr. D—, colonial functionary, had contracted dysentery at Hué in May, 1889. Notwithstanding twice returning to France and the use of the waters of Bassang he was always suffering and was subject every moment to relapses. He lost 24 lb. in weight. In January, 1893, he began a series of sixty washings—result, complete amelioration. In July, 1894, two years later, Mr. D— left Pondicherry, always progressing and having regained his weight.—Case 5: Miss X—, eighteen years of age, Eurasian, had in 1891 dysentery at Hyderabad, after which period she never passed two months without a relapse. In May, 1891, series of washings up to fifty only. Perfect amelioration. I heard of her a year later and the cure was maintained.—Case 6: Rev. Father —, missionary in Tanjore, contracted dysentery in 1890. Afterwards he constantly had constipation, alternating with mucous diarrhoea and tenesmus. A series of sixty washings resulted in a complete cure. He was able to resume his hard work in 1892, and to-day (September, 1894) he came to show himself to me, and he was stout, fresh and vigorous.—Case 7: Mr. —, Controller of the Revenue Accounts at Pondicherry, had acute dysentery in 1888, followed by constant relapses. In July and August, 1893, he underwent a series of fifty-six washings, with immediate relief, maintained now in September, 1894.—Case 8: Mrs. E—, twenty-one years, Eurasian, had dysentery in repeating form at the age of fifteen, was very weak and chlorotic. In October, 1893, she began a series of

fifty washings, and complete cure followed ten. In June, 1894, she went away to Europe strong and fat, bearing without difficulty the commencement of pregnancy.

"I have, on my own account, shortened the clinical description of the above cases, the details being the same for each of them. I must now indicate the way of proceeding methodically with the antiseptic washings of the large intestine, as this is important, and the final success or failure may depend exclusively on good and rational application. A first enema of tepid water washes as completely as possible the large intestine. After evacuating this the antiseptic washing should be applied, adding to it 20 or 30 minims of laudanum. This ought to be retained for two or three minutes, five being the maximum. One litre at least of liquid is indispensable when the treatment is for an adult. I always advise patients to use the washing in the morning, as soon as they awake, as, if they feel any cramps, they can go back again at once to the pleasant warmth of the bed they have just left, for cramps sometimes make this treatment difficult. I always recommend the treatment to be continued till the sixtieth washing, and that has on every occasion been enough. I have been guided in these remarks throughout by the personal result of a long series of washings which I myself took, which were interrupted only by my departure to India. My full recovery has been an unexpected result to myself, and remains the inciting example I can always offer to those suffering from chronic dysentery, who, more or less, are disheartened and sceptical regarding new modes of treatment. He who has followed my example has never been deceived; and, guided by a hope of being of service to a large number of sufferers, I have made this attempt to inform colonial medical men the results I have obtained in so tenacious an affection as repeating dysentery by a method of treatment which, in my hands, has shown itself to be as easily bearable as it is quickly effective."

Note on the Influence of Railways on the Dissemination of Cholera.

Surgeon-Major J. T. LEWIS, M.D., read a paper on this subject. He said: "Any influence which railways may have in promoting the spread of cholera would be expected to show itself in one or both of the following ways: (1) by a more rapid extension of epidemics, as compared with those which occurred before railways were opened, the extension taking place especially along lines of the railway which pass through centres of the disease; and (2) by disproportionate prevalence of the disease in places lying on or near lines of railway. Do railways disseminate epidemics of cholera more rapidly? An examination of the history of epidemics of cholera both in India and Europe shows that railways have had little, if any, effect upon their progress. Obviously individual cases have been carried further than would have been possible before the introduction of railways; for example, a man may have imbibed cholera poison just before taking his seat in a train, and may travel 200 miles or more before symptoms are developed, whereas before the days of railways he would not have gone further than ten or fifteen miles in a bullock cart. But such cases as this do not appear to affect the subsequent course of the epidemic; they neither accelerate its progress nor determine its direction. During recent epidemics of cholera in Europe it frequently happened that individuals travelled considerable distances by rail from the place at which they had received the infection before the disease showed itself in them, but that no other case occurred in the towns or villages where they eventually either died or recovered. To quote an instance in India: At Meerut, in 1869, a sepoy was removed moribund from a railway carriage and was carried to the lines of the 36th Native Infantry Regiment before he died. But no other case occurred amongst the native troops at Meerut until a fortnight later, when the advancing epidemic reached that place.¹ Again, on April 14th, 1893, five men attacked with cholera were removed from a train at Saharanpur. Three of these died, but no epidemic ensued in Saharanpur. Does epidemic cholera in its advance specially follow lines of railway? The history of epidemic cholera in India does not show that the disease advances along lines of railway rather than by other roads. Sometimes, on the contrary, a line of railway remains outside although close to an epidemic area. The map of the epidemic of 1869 is a very striking illustration of this. The disease that year attacked Allahabad on March 21st, advanced slowly to Delhi, keeping almost exclusively to the south and west of

the railroad, until at Delhi it left the line altogether and travelled to Lahore by way of Hansi and Hissar, parallel to, but distant 100 miles from, the line. The country between Meerut and Amritsar, 250 miles in length, although traversed daily by trains, remained absolutely exempt from the disease. It is a fact, be the explanation what it may, that during the epidemic of 1869 there existed a large area of country extending from Shahjahanpur to Amritsar, 400 miles in length, traversed by every means of communication, and in which Hurdwar itself is included, which, nevertheless, was free from cholera, which was prevalent in adjoining districts. Other similar instances are to be found in the bewildering pile of literature which has grown up regarding cholera in India, and in voluminous reports in the United States. I have arrived at the following conclusions. 1. Railways convey patients suffering from cholera to places which they would not have reached in the days before railways were opened, but such cases do not by themselves determine, or even appreciably influence, the course of the epidemic. 2. Railways are a great safeguard to those who use them in order to escape from an infected locality; and as they constitute the quickest means of removing a large collection of people from any place in which cholera has appeared their influence, so far as these people are concerned, is eminently salutary, and the consequent introduction of some cases of cholera to previously non-infected places is dangerous only in so far as the sanitation of these may be defective. This statement is based not only upon the records of Indian experience, but also upon those of the European epidemics of 1884 and 1885. In a supplement to the Fifteenth Annual Report of the Local Government Board, p. 107, the following passages occur. 'The experience of cholera in England justifies a belief that the presence of imported cases of the disease at various spots in the country will not be capable of causing much injury to the population if the places receiving infection have had the advantage of proper sanitary administration.' Again: 'Cholera in England shows itself so little contagious that if reasonable care be taken where it is present, there is almost no risk that it will spread to persons who nurse and otherwise closely attend upon the sick.' One more extract from the same report: 'Thus, when a case of cholera is imported into any place the disease is not likely to spread, unless in proportion as it finds locally open to it certain facilities for spreading by indirect infection.' These and other references in this paper to European and American experience are not, I venture to think, irrelevant, because they show that those who have had especially favourable opportunities of observing cholera there have arrived at conclusions which agree with our experience of the disease in India."

Infectious Pneumonia.

Surgeon-Major DUNCAN, M.D., in his paper on Infectious Pneumonia, considered the nature of an epidemic of pneumonia which fell under his observation ten years ago. He said: "On Nov. 25th, 1885, the 23rd Pioneers arrived at Umballa from the Pishin Valley. From Nov. 25th, 1885, to April 26th, 1886, thirty-three cases of pneumonia occurred. By months they were thus distributed: four in November, nine in December, five in January, five in February, five in March, and five in April. Many surmises as to the cause of the affection were made: 1. That the regiment was inadequately clothed and that the men caught cold. Now the regiment was, in fact, one of the best clothed in the Native Army. In addition to their ordinary dress each man had been provided with a thick sailor's jersey. 2. It was held that the regiment had returned from Pishin broken down in health. The following was the daily admission rate for the regiment from 1881 to 1886: in 1881, 39.65 per 1000; in 1882, 37.29 per 1000; in 1883, 22.53 per 1000; in 1884, 18.55 per 1000; in 1885, 31.41 per 1000; and in 1886, 19.62 per 1000. At first sight the admission rate for 1885 seems greatly in excess of that for 1883 and 1884, but a more minute examination showed the following facts; the great bulk of the regiment was in the Hurnai Pass up to April 18th; from April 18th to Nov. 16th the regiment was in the Pishin Valley; and from the latter date it travelled to Umballa, reaching this place on Nov. 26th. Now the rate of the headquarters admission from Jan. 1st to April 18th was 25.74; from April 18th to Nov. 26th, 19.21; and from Nov. 27th to Dec. 31st, 39.40. Hence the large bulk of admissions occurred after the regiment had returned from Pishin, whilst in Pishin the admissions were only slightly in advance of those of the preceding year. Thirdly, a white fog that prevailed in the lines in January was held in some way to

¹ See Dr. Bryden's report upon the cholera epidemic of 1869, page 53.

have caused the disease, much in the same way as a yellow fog was evoked to account for the cholera by some authorities in Egypt in 1883. Unfortunately, however, for this idea, the pneumonia continued when the white fog had disappeared, much in the same way as cholera has appeared when there has been no yellow fog. Fourthly, it might have been due to the cold from December to February. Cold, however, could not have caused the cases later. The temperature was taken in my hospital three times daily. Not to prove wearisome with the tables I will merely state the temperature found at noon. In March it rose from 71° to 80°; in April from 75° to 94°. As cases still continued to come into hospital, I determined to treat them as infectious. Under my advice the lines were evacuated and the men placed under canvas. The lines were then disinfected with sulphurous acid gas for six hours, every aperture being closed up, and on the day following the fumigation they were freely ventilated. On the third day the lines were reoccupied. By April 14th all the lines with the exception of those of the band had been disinfected. On April 14th case thirty-one, that of a musician, occurred. On the 15th the band went into tents. Two cases subsequently occurred on April 18th in the married lines; one on April 26th in the band lines. Both these cases occurred nine days after the lines were reoccupied, or eleven days after they had been evacuated for disinfection. But if pneumonia be a specific infectious fever it will have a period of incubation. This period, it may be not too much to assume, may be as long as eleven days, and thus the disease may have been contracted before the lines were disinfected. This theory receives support from the fact that during the same months measles had been present in the married lines. Now, subsequent to the disinfection three cases of measles occurred—two on April 17th in lines disinfected on the 13th and the third within a week from the disinfection. The incubation period of measles is stated to range from seven to twenty-one days; hence it is probable that all these cases were beginning as regards incubation before the lines were disinfected."

Surgeon-Major DUNCAN then briefly put forward his detailed reasons for considering the cases to have been epidemic and infectious in their nature, and not merely of local inflammation. He pointed out that if the affection had been merely a local one, on the return of the normal temperature the lungs would have been found to have quickly cleared up. He considered that the idea that cold especially predisposed to pneumonia was conclusively proved to be erroneous by Dr. Sanders of America. In a paper published in the *American Journal of the Medical Sciences* for July, 1882, he showed the disease to be more frequently met with and more common in warm than in cold climates, and in hot than in warm climates, showing a gradually increasing ratio from the Poles to the Equator, and that pneumonia, other things being equal, increases uniformly in frequency the nearer we approach the tropics.

Carlsbad and its Thermal Waters for Anglo-Indians.

Surgeon-General Sir J. FAYRE, M.D., F.R.S., contributed a paper on this subject. After exhaustively reviewing it from all the ordinary points of view, telluric, geographical, thermometrical and hygienic (we regret that space prevents us from printing the paper in full), Sir Joseph Fayre noticed the conditions for which Carlsbad is likely to be useful to Anglo-Indians. He said: "The waters are indicated in the following disorders. In congestion and functional derangement of the liver, in catarrhal jaundice, in gall-stones or inspissated bile, and in chronic hepatic enlargement in which serious structural change of the amyloid or other degenerative processes have not taken place; in chronic engorgement of the portal system, in catarrhal conditions of the mucous membrane of the intestines and congestion of the hæmorrhoidal vessels; also in habitual constipation, incipient hæmorrhoids, and even in the earlier stages of tropical diarrhoea; in diseases of the spleen, such as chronic hyperæmia and enlargement, resulting from malarial poisoning; in chronic gastric catarrh, in cardialgia or gastralgia, dyspepsia, dilatation of the stomach; in those forms of albuminuria which take place as the result of abdominal plethora and changes in the blood due to malarial poisoning; in renal and vesical gravel; in lithiasis; also in chronic catarrh of the bladder and in hyperæmia of the prostate gland, and in some hyperæmic conditions of the uterus and its appendages; in all conditions in which the gouty diathesis manifests itself,

and in general abdominal plethora and in obesity, whether of the abdomen or of the body generally. In the earlier forms of diabetes there seems little doubt, from the testimony of eminent authorities, that benefit may be derived. But Carlsbad is to be especially recommended to those who, after protracted residence in India or other malarial climate, suffer from occasional recurrences of malarial fever, with consequent derangement of function and even alteration in the normal condition of the liver, spleen, and other abdominal viscera, who, without suffering from any positive disease, are failing in health, have impaired digestion, a distended condition of the abdomen, increasing fatty deposit in the omentum, and a tendency to fatty degeneration of the muscular system generally; who find themselves languid and depressed, unequal to much physical or mental exertion, show indications of incipient æmia, suffer from dyspœa, from rheumatic or gouty pains, irregular action of the bowels, congestion of the portal system, and distended hæmorrhoidal vessels—a state of things perhaps in some cases aggravated by excesses or irregularities of diet or the neglect of due precautions as to the quantity or kind of alcoholic stimulants. Such are the conditions in which an early recourse to Carlsbad and a judicious selection of some intermediate health resort before returning to the ordinary mode of life are likely to confer benefit. Indeed, almost every European not the subject of organic disease who has spent many years in India would do well to avail himself of the resources of Carlsbad before he enters upon the new course of life which lies before him, whether he be returning to India from furlough or retiring to spend the remainder of his life at home."

THE GRIEVANCES OF POLICE SURGEONS.

ON Thursday morning last a deputation from the United Kingdom Police Surgeons' Association was received by the Home Secretary, Mr. Asquith, having for its object to urge upon him the necessity for some reform (1) in regard to the inadequacy of the remuneration allowed to medical witnesses attending sessions from a distance; (2) in regard to the rules for the examination of accused persons in cases of criminal assault; (3) in regard to the suitability of appointing police surgeons throughout the country where none exist; and (4) in regard to the examination of cases where death may have been due to poison, violence, or criminal neglect.

The following gentlemen formed the deputation:—Mr. Holmes, London; Mr. Bond, London; Mr. Lowndes, Liverpool; Mr. H. Nelson Hardy, London; Mr. Heslop, Manchester; Mr. Hopkins, Bath; Dr. Brown, Bristol; Mr. Stephens, Brighton; Dr. Maybury, Portsmouth; Mr. Houchin, London; Mr. Roberts, London; Dr. Grosvenor, London; Mr. Scatliff, Margate; and Mr. Mitchell Roocroft, Wigan.

Mr. H. NELSON HARDY introduced the deputation, referring to the many letters which had appeared in THE LANCET and other medical journals on the subject, and the following gentlemen addressed the Home Secretary: Mr. Bond, Mr. Lowndes, Mr. Holmes, Mr. Hopkins, Mr. Heslop, Dr. Brown, Dr. Maybury, and Mr. Roocroft.

Mr. ASQUITH, in reply, said: With reference to the question of examination in cases of criminal assault it would be desirable that a circular should be issued from the Home Office calling attention to the rules already in force for the guidance of the Metropolitan Police, and pointing out to the various Watch Committees the expediency of issuing the same or similar regulations to their own courts. With regard to the fourth point, he thought police surgeons were the proper persons, and likely to be more competent than medical officers of health, to carry out these duties, but the matter did not quite come within the jurisdiction of the Home Office. The question of remuneration was no doubt an important one. The scale for remuneration of witnesses was fixed in 1858. He did not wish to say that this was a just scale, but the fact that it substantially remained the same as when first fixed showed that the various Home Secretaries since that time had not cared to burn their fingers by altering it. He entirely agreed that the scale of one guinea was inadequate, but the same might be said for every single item of the whole scale as applied to most witnesses. He did not say that the case of medical witnesses was not a harder one, but each individual should require his

own employers (such as the Watch Committee, &c.) to make some provision to supplement the inadequate payment. He would be very glad to see the police authorities of the country recognise this. As to the lack in some important counties and boroughs of recognised, accessible, and generally known practitioners, not only for attendance on the force, but for cases where expert services were required, he would consider whether it was not desirable to call attention in a circular to the need of attaching to every police force some recognised police surgeon.

Mr. BOND having thanked Mr. Asquith, the deputation withdrew.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the First Examination of the Board, in the subjects indicated, at the quarterly meeting of the Examiners under the four years' regulations:—

Part I., Chemistry and Physics:

Battiscombe, Eric George, London Hospital.
Boulton, Thomas, Owens College, Manchester.
Broughton, Louis Charles Southall, Mason College, Birmingham.
Griffiths, David Roger Thomas, Guy's Hospital.
Hiffe, Caris William, Owens College, Manchester.
Oldham, Sam Drayton, Owens College, Manchester.
Rooth, James Augustus, St. George's Hospital.
Watkins, Alan Percival, Cambridge University and University College Hospital.

Part II., Materia Medica and Pharmacy:

Bascombe, Edwin Cecil Dare, Middlesex Hospital.
Betts, Edward Hetley, St. Bartholomew's Hospital.
Broughton, Louis Charles Southall, Mason College, Birmingham.
Chambers, John Miles, St. Thomas's Hospital.
Cheese, John William, University College, London.
Chevallier, Claude Lionel, St. Thomas's Hospital.
Clements, John Hall, Mason College, Birmingham.
Collyer, Bertram Joseph, St. Bartholomew's Hospital.
Cooper, Edward Harold, London Hospital.
Curtis, Percy James, Guy's Hospital.
Davies, Thomas Stanley, St. George's Hospital.
Distin, Ernest John, King's College, London.
Eastman, Julius Daniel, Owens College, Manchester.
Eastment, Alan Grant, Middlesex Hospital.
Ellery, Henry George, Queen's College, Cork, and Middlesex Hospital.
Evans, Alexander, St. Mungo's College, Glasgow.
Evans, Charles Robert, Guy's Hospital.
French, Louis Alex. Weatherhead, University College, London.
Goodridge, Walter Lisle Taylor, Guy's Hospital, Durham, and University College, London.
Hair, Alan, University College, London.
Hodges, George William Cecil, St. George's Hospital.
Johnson, Edward Stanley, St. Mary's Hospital.
Knox, Robert George, King's College, London.
MacWatters, John Courtenay, University College, Bristol.
Mason, Sydney Herbert, Mason College, Birmingham, and Guy's Hospital.
Mellish, John Stafford, St. George's Hospital.
Newman, Herbert Robert Cambridge, University College, Bristol.
Owen, John Griffith, Charing-cross Hospital.
Owen, Lanyon Edward, University College, London.
Parlett, Frank, private study.
Rivers, Walter Courtenay, Charing-cross Hospital.
Rogers, Reginald James, University College, Bristol.
Shaw, Kenneth Rodas Devaigues, Owens College, Manchester.
Smith, Julius Hodgetts, St. Thomas's Hospital.
Smith, Montague, Middlesex Hospital.
Stevenson, Walter Brodie, St. Mary's Hospital.
Sykes, John Lewis, London Hospital.
Thorpe, Robert Smith, Owens College, Manchester, and Guy's Hospital.
Tomkins, Arthur Kenelm Digby, Mason College, Birmingham.
Vines, Sidney Kendrick, Mason College, Birmingham.
Watton, Sydney Herbert, Owens College, Manchester.
Wills, Edward Channing, University College, Bristol.
Woodman, William James, St. Mary's Hospital.

Part III., Elementary Anatomy and Elementary Physiology:

Allan, Herbert William, Cambridge University.
Anderson, Lewis Pemberton, University College, Liverpool, and Owens College, Manchester.
Atkinson, Frederick Cecil Edgar, St. George's Hospital.
Charlesworth, Edward Adams, Middlesex Hospital.
Denyer, Stanley Edward, Cambridge University.
Duncan, James Simpson, Westminster Hospital.
Garman, Joseph Marcus, London Hospital.
Gillmore, Arthur Ernest, Cambridge University.
Micklethwaite, John, Firth College, Sheffield.
Richardson, Joseph James Daly, Guy's Hospital.
Simms, Clifford Greville, Middlesex Hospital and Mr. Cooke's School of Anatomy and Physiology.
Spencer, William Northey, University College, Bristol.
Whittingham, Arthur Herbert, Cambridge University and St. Mary's Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentleman, having previously passed the necessary examinations, and having now attained the legal age of twenty-five years, was, at the quarterly meeting of the Council on Thursday, the 10th inst., admitted a Fellow of the College:—

Beidloe, David Morgan, L.R.C.P. Lond., Guy's Hospital; diploma of Member dated May 11th, 1893.

FOREIGN UNIVERSITY INTELLIGENCE.—*Göttingen*: The rank of Professor has been granted to Dr. Hildebrand, *privat-docent* in Surgery, to Dr. Droyren, *privat-docent* in Midwifery, and to Dr. Nicolaler, *privat-docent* in Medicine.—*Innsbruck*: Dr. Carl Mayer of Vienna has been appointed Extraordinary Professor of Neurology and Psychiatry.—*Munich*: Dr. Buengner has been appointed Extraordinary Professor of Surgery.—*Vienna*: Professor Schnabel of Prague has been appointed Professor of Ophthalmology in succession to Professor Stellwag von Carion, retired. Dr. Emil Schütz of Prague has been recognised as *privat-docent* in Medicine. Great disappointment has been occasioned by the announcement that the Government have abandoned the plan of acquiring the Alser Barracks for the purpose of enlarging the General Hospital.

DINNER OF THE LARYNGOLOGICAL SOCIETY OF LONDON.—This society held its third annual meeting on Wednesday, 9th inst., and in the evening the members dined together at the Café Royal, Dr. Felix Semon, the President, being in the chair. Among the guests were Sir J. Russell Reynolds (President of the Royal College of Physicians of London), Sir William MacCormac, Sir George Johnson, Signor Manuel Garcia, and others. The toast of "The Guests" was acknowledged by Sir J. Russell Reynolds and Dr. Ord, who in return proposed "Success to the Laryngological Society," coupled with the name of its president. Sir George Johnson responded for "The Honorary Members." The health of Signor Manuel Garcia, the inventor of the laryngoscope, was drunk with the greatest enthusiasm, and Signor Garcia, now in his ninety-first year, replied in appropriate terms.
